Motivation – Why Chesapeake Bay?

The Chesapeake Bay:

- Largest estuary in U.S.
- Benefits derived from Bay > $100 Billion annually
- Major anthropogenic impacts threaten Chesapeake’s economic/social services
- Additional impacts of climate change are not yet known
- One of longest & most comprehensive data sets (1985-present)
Motivation – Why focus on hypoxia?

Hypoxic (low oxygen) waters:

- Impact ecological resources in Bay, particularly demersal fish (low catches where DO < 3 mg/L)
COMT Chesapeake Hypoxia Objectives:

- Evaluate short-term forecast skill of hypoxia events
- Transition hypoxia forecasts to operations
- Work with stakeholders to better understand how they prefer to receive this forecast information
- Evaluate scenario-based forecasts
  - How will decreased nutrient inputs impact hypoxia?
  - How will climate change impact hypoxia?
• **Short-term operational forecasts** (M. Friedrichs/A. Bever)
  - Review of Year 3 accomplishments
  - Quasi-operational forecasts (VIMS website)
  - Operational forecasts (dev) (CBOFS website)
  - Additional skill assessment of forecasts

• **Improvements to Hypoxia-SRM** (M. Scully/C. Friedrichs)

• **Seasonal patterns in P biomass & PP variability** (R. Hood/H. Wang)

• **Scenario-based operational forecasts** (I. Irby/M. Friedrichs)
  - Evaluating uncertainty in forecasts of nutrient reduction impacts
  - Assessing impacts of climate change on nutrient reduction impacts

• **Year 5 plans** (M. Friedrichs)
Previous work identified and compared skill of multiple Chesapeake Bay oxygen models

**Models:**

- Eight models were compared, including multiple physical and biogeochemical variants

**Available data:**

- Models were assessed by monthly data (semi-monthly in summer) at multiple locations throughout Bay from 1985-present
- Data includes S, T, DO and multiple other ecological parameters
Results:

Year 2-3: Multiple model comparison (Irby et al. 2016):
- Simple models performed as well as more complex models
- Mean of multiple models performed best

Year 3: Examined nowcast vs. hindcast skill of CBOFS bottom DO:
- Nowcast bottom DO skill > hindcast bottom DO skill!

Year 3: Quasi-operational forecasts came online on VIMS website:
- Focus Groups & Stakeholder Workshops
Stakeholder Workshop summary:

- Strong enthusiasm for hypoxia forecasts as complementary tool with other information sources
- Several captains already use real-time observations for planning (e.g., water clarity, temperature, wave heights) and/or short-term model forecasts (e.g., currents from CBOFS)
- Little interest in hypoxia forecasts beyond 2-3 days because of limited trust in detailed weather/wind forecasts beyond 2-3 days
- Provided specific feedback on website presentation
Year 4 Forecast improvements:

- Forecast now uses CBOFS operational forcing
- Forecast now shows mean of two models
  - SRM = Simple Respiration Model
  - ECB = Estuarine Carbon Biogeochemistry model
- SRM has been improved with seasonally variable respiration rate
- New (more detailed) color scale
- Improved appearance on mobile devices
Blues $\rightarrow$ High bottom oxygen
   = Good bottom water
   = Bottom fish and crabs

Yellow/green $\rightarrow$ Moderate to low oxygen
   = Poor bottom water
   = Fewer bottom fish and crabs

Red/orange $\rightarrow$ Very low bottom oxygen
   = Bad bottom water
   = No bottom fish or crabs
Friday’s Nowcast

Bottom Oxygen: Nowcast
July 28, 2017

White areas indicate no results where model bathymetry < 5m in depth

Friday’s Forecast

Bottom Oxygen: Forecast
July 30, 2017

Chesapeake Hypoxia Forecast: www.vims.edu/hypoxia
Blue $\rightarrow$ Increasing oxygen 
(Improving bottom water in **western** Bay)

Red $\rightarrow$ Decreasing oxygen 
(Degrading bottom water in **eastern** Bay)

Due to forecast of strong NNW winds over the weekend
VIMS’ New Forecast Tool Can Help Anglers Find Good Fishing

VIMS’ new dead zone forecast tool can help anglers find good fishing.

VIMS’ new forecast tool can help anglers find good fishing

From July 2017

• **Year 5 plans** *(M. Friedrichs)*
Additional Year 4 objectives:
• How does the nowcast skill of SRM vs. ECB compare?
• How does the forecast skill of both models degrade over 6 - 48 hours?

Methods:
• Improve SRM by imposing seasonally varying respiration rate
• Apply identical forcing to both models
• Run 2.25 day simulation every six hours for the full 2.75 years, generating continually overlapping nowcasts and forecasts (6h, 12h, 18h, 24h, 30h, 36h, 42h, 48h)
Compare nowcast skill of ECB vs. SRM

Chesapeake Hypoxia Forecast - Testing
ChesROMS-ECB and ChesROMS-SRM produce nowcasts with similar skill (and that are equally skillful as hindcasts)

WHAT ABOUT FORECAST SKILL?

- Do forecasts predict same timing of DO events as nowcasts?
- Are forecasts skillful enough at predicting relatively large changes in DO, such that stakeholders can use the forecasts to plan their daily activities?
Methods:

- Significant “events” were defined as daily averaged bottom DO changing by $\geq 2\text{mg/L}$ over $\leq 2$ days
Methods:

• Significant “events” were defined as daily averaged bottom DO changing by $\geq 2\text{mg/L}$ over $\leq 2$ days.

• Error (lag/lead time) of forecast is determined by time-shifting the forecast output and determining the time shift with the highest $r^2$ value between the nowcasted and forecasted DO.

• Examined results at 11 stations for both models.
Chesapeake Hypoxia Forecast - Testing

Forecast leads nowcast by 4.3h, for SRM at CB4.1C
Error in 48 hour forecast is ~6h (ECB) to 7.5h (SRM)
Next year’s work (Year 5):

- Complete transition of hypoxia forecasts to operational CBOFS site (AJ Zhang)
- Provide forecast information for posting on MARACOOS Ocean Obs site (K. Knee)
- Examine feasibility of improving hypoxia forecasts by incorporating bottom oxygen data (A. Bever)
- Examine feasibility of including habitat suitability information for HABs & pathogens (R. Hood)
- Improve presentation of information provided on VIMS site through outreach with end-users (S. Musick)
  - Add salinity, temperature (HABs, vibrio?)
  - Add time series
  - Add climatological information
• **Short-term operational forecasts (M. Friedrichs/A. Bever)**
  - Review of Year 3 accomplishments
  - Quasi-operational forecasts (VIMS website)
  - Operational forecasts (dev) (CBOFS website)
  - Skill assessment of forecasts

• **Improvements to Hypoxia-SRM (M. Scully/C. Friedrichs)**

• **Seasonal patterns in P biomass & PP variability**
  (R. Hood/H. Wang)

• **Scenario-based operational forecasts (I. Irby/M. Friedrichs)**
  - Evaluating uncertainty in forecasts of nutrient reduction impacts
  - Assessing impacts of climate change on nutrient reduction impacts

• **Year 5 plans (M. Friedrichs)**
Goals and Motivation:

- Develop a method for estimating Primary Production (PP) from time-series measurements of dissolved oxygen ($O_2$) that can provide estimates of fundamental rates to rigorously test biogeochemical models.
- Incorporate a light-dependent formulation for PP into a simple model for $O_2$ that is suitable for operational forecast modeling.

Outline:

- Method for estimating PP and fundamental rates from observed $O_2$.
- Validation of the method with output from biogeochemical model (ECB).
- Modeling results from simple 1-term model with improved representation of biological processes (oxygen production).
Method for Estimating PP from $O_2$ Time-Series

$\alpha = \text{init. slope of P-I curve}$
$P_m = \text{Max. growth rate}$
$I = \text{Irradiance (Light)}$

\[
\frac{dO_2}{dt} = P_m \tanh\left(\frac{\alpha I}{P_m}\right) + C
\]

(Jassby & Platt 1976)

**Data Needs:**

- Continuous (hourly) measurements of near surface $O_2$ (CBIBS buoys)
- Continuous estimates of incoming solar radiation (NARR model)

**Procedure:**

- Calculate time-rate of change of oxygen ($dO_2/dt$) from buoy data.
- Estimate coefficient ($C$) by taking the average value of $dO_2/dt$ at night (this represents both biological drawdown and physical processes).
- Perform least-squares fit to $P_m \tanh(\alpha I/P_m)$ to obtain estimates of $P_m$ (maximum phytoplankton growth rate) and $\alpha$ (initial slope of P-I curve) over a 20-day moving window.
Method for Estimating PP from O$_2$ Time-Series

Example from CBIBS Goose’s Reef Buoy for July-August 2013

- Instantaneous $dO_2/dt$
- Bin-averaged $dO_2/dt$
  
  \[ P_m \tanh \left( \frac{\alpha I}{P_m} \right) + C \]

- Daily Variation in Light
- Daily Variation in $dO_2/dt$
Application of Method to ECB Output

- ECB = direct PP output
- PP est. = $P_m \tanh\left( \frac{\alpha I}{P_m} \right)$ inferred from near-surface ECB $O_2$

y-axes are PP in units of $O_2$/vol/time
Estimates of Primary Production from CBIBS Buoys

Light limited

Increasing Nutrient Limitation

PP in units of O$_2$/vol/time
Evidence for Light Limitation at Susquehanna Buoy

![Graph showing primary production and turbidity over time from January 2015 to January 2016. The graph compares the ratio of primary production and turbidity (PP/max(PP) and NTU/max(NTU)) over the months. There are two subplots: the upper plot shows the monthly variation of these ratios, and the lower plot shows a scatter plot of primary production (PP) versus turbidity (NTU).]
Simple $O_2$ Model including Primary Production

$$\frac{\partial O_2}{\partial t} = PP + CR + u \nabla O_2 + \frac{\partial}{\partial z} \left< O'_2 w' \right>$$

$PP = P_m \tanh \left( \frac{\alpha I}{P_m} \right)$

Temperature dependent maximum growth rate

Temperature dependent slope of P-I curve

Depth-invariant seasonally-varying oxygen consumption. Modeled as simple Gaussian function with max at end of July

Relationships derived from CBIBS Buoys

Max Growth Rate ($P_m$)

Slope P-I curve ($\alpha$)

Temperature (C°)

mmoles$O_2$ m$^{-3}$ s$^{-1}$

$10^{-5}$ mmoles$O_2$ m$^{-3}$ s$^{-1}$
Previously, the Simple Respiration Model assumed that surface oxygen concentration was maintained at saturation value.

New formulation captures time variations (including super-saturation) in a much more realistic way.
Model Comparison of Bottom O₂ (Scully 2013 data)

Overarching Questions:

• Do current generation biogeochemical models capture observed seasonal patterns in phytoplankton biomass and primary production variability in Chesapeake Bay?

• What is the role of lateral transport in supplying organic matter to the deep channel of the mainstem Chesapeake Bay?

• Can we use our BGC model as a dynamic interpolator to provide insight into the temporal and spatial variability in denitrification in Chesapeake Bay?
Overarching Questions:

• Do current generation biogeochemical models capture observed seasonal patterns in phytoplankton biomass and primary production variability in Chesapeake Bay?

• What is the role of lateral transport in supplying organic matter to the deep channel of the mainstem Chesapeake Bay?

• Can we use our BGC model as a dynamic interpolator to provide insight into the temporal and spatial variability in denitrification in Chesapeake Bay?
Variability of biomass and productivity

Classic Conceptual Model of Biomass and Production Variability:

• Freshet drives the spring diatom bloom and leads to export to the bottom.
• Increasing summer temperatures lead to remineralization of organic matter on the bottom.
• Upward diffusive mixing and transport of nutrients to the surface during summer leads to high summer production.
The spring diatom bloom is associated with freshet, but it's not a productivity maximum. During summer, there is maximum productivity. This summer production is fueled largely by recycling of organic matter from the bottom that was put there during spring.

Also see a shift in size: large diatoms in spring -> smaller flagellates and dinoflagellates in summer.
Variability of biomass and productivity

Model Configuration (ChesROMS BGC):

- Xu et al. (2012)
- Grid: 100x150x20
- Brown et al. (2013), Wiggert et al. (2017)
- Fennel et al. (2006) with water column and benthic denitrification.
Variability of biomass and productivity

Modeled Phytoplankton Biomass:

Models Capture:

- Spring bloom
- Deep chlorophyll accumulation in Spring
- Low biomass during summer
Modeling Primary Production Rate:

• Model captures the seasonal variability of the primary production in some years: e.g., 1994 highest production during summer as observed.
Variability of biomass and productivity

Modeling Primary Production Rate:

- But not in others: e.g., in 1991 see a dramatic drop in the summer which is not consistent with observations.
Role of River Forcing:

- River discharge plays a role in this interannual variability.
- Years with high river nutrient loading during summer tend to capture observed high summertime primary production (e.g., 1994).
- Years with low nutrient loading during summer tend to have primary production rates that are too low during summer (e.g., 1991).
We hypothesize that there is insufficient upward diffusion and mixing of nutrients to support high summertime production in our models when river nutrient inputs during summer are low.
Conclusions:

- Models can capture observed seasonal and vertical variability in phytoplankton biomass but they do not consistently capture seasonal primary production variability.

- Models require lateral nutrient inputs from rivers to maintain high production during summer.

- Low lateral supply during summer results in nutrient limitation and unrealistically low summertime production.

- We hypothesize that there is insufficient upward diffusion and mixing of nutrients to support high summertime production in these models when summertime river nutrient inputs are low.
