The Center for Conservation Biology is an organization dedicated to discovering innovative solutions to environmental problems that are both scientifically sound and practical within today's social context. Our philosophy has been to use a general systems approach to locate critical information needs and to plot a deliberate course of action to reach what we believe are essential information endpoints.

## EXECUTIVE SUMMARY

Large numbers of diurnal raptors from breeding populations across northern latitudes migrate south along the Atlantic flyway to reach winter destinations from southeastern North America to southern South America. Many of these birds become concentrated within geographic bottlenecks where they rest and forage. Each fall since 1978, staff, students, and associates of the Center for Conservation Biology at the College of William and Mary have trapped diurnal raptors near the tip of the Lower Delmarva Peninsula. The research objectives of this project continue to be 1) to monitor trends in the migration of several raptor species, 2) to learn more about the natural history of migratory raptors, and 3) to add to our understanding of migratory movements and pathways.

During the fall of 2003, the Wise Point Station was operated on 52 days between 9 September and 23 November for a total of 359 hours. A combination of mist nets, bow nets, and dho-gaza nets were used in conjunction with lure birds to trap migrating raptors. A total of 516 raptors of seven species was banded resulting in an overall capture rate of 1.4 birds/operation hr. The project has recorded lower overall capture rates in only 2 of the previous 15 years. The 2003 season continued a downward trend in overall capture rate. Since 1989, capture rate has declined significantly at an average rate of approximately 6%/year. A decline in the capture rate of Sharp-shinned Hawks appears to be solely responsible for the decline in overall rate. The proportion of total captures accounted for by Sharp-shins has declined from more than 60% of total captures in the early 1990's to less than 30% in recent years. The population-level implications of continued declines in capture rates for Sharp-shinned Hawks within the mid-Atlantic remain unclear.

Six birds that were banded at Wise Point during the 2003 season have been recovered elsewhere. This includes 2 Sharp-shinned Hawks, 3 Cooper's Hawks, and 1 Merlin. Recoveries ranged from Dover Delaware to Marathon Florida. The Merlin was banded on the 8<sup>th</sup> of October and recovered in Marathon, FL just 6 days later. A total of 19 birds were captured that had been banded previously elsewhere. These included a young, male Peregrine that was color banded in Canada.

## **BACKGROUND**

### **Context**

Each fall, large numbers of diurnal raptors from breeding populations across northern latitudes migrate south along the Atlantic Coast to reach winter destinations ranging from southeastern North America to southern South America. For a host of reasons, these birds often become concentrated around significant physical barriers. The mouth of the Chesapeake Bay is one of the largest physical barriers along the Atlantic Flyway. Many taxonomic groups of birds become concentrated along the lower Delmarva Peninsula as they reach the open water of the Bay. For this reason, the lower Delmarva represents one of the best locations in the region to observe and study fall migrating birds.

Over the years, local interests have led to the development of several migration monitoring programs along the Lower Delmarva Peninsula. The Kiptopeke Beach Banding Station (located on the property now designated as Kiptopeke State Park) was established in 1963 by several members of the Virginia Ornithological Society to band and monitor passerine migrants. The station is now one of the longest running migration banding operations in eastern North America and has processed nearly 290,000 migrants. In the fall of 1994, the Center for Conservation Biology initiated a program to band Northern Saw-whet Owls near the tip of the peninsula and since that time have processed more than 2,500 birds. Many different research projects focused on avian migration have been conducted within this location over the past several decades.

Several species of diurnal raptors migrate along the coastal corridor and move through the lower Delmarva in large numbers. Each fall since 1978, staff, students, and associates of the Center for Conservation Biology at the College of William and Mary have trapped diurnal raptors on the Lower Delmarva. Trapping was initiated on Fisherman's Island in the late 1970's and was later expanded to Wise Point. The Wise Point site, located on the Eastern Shore of Virginia NWR, is ideal because large numbers of raptors circulate for a variable length of time before crossing the mouth of the Chesapeake Bay. The early trapping program was initiated to monitor the migration of the endangered population of Peregrine Falcons. Due to the valuable information being collected on other raptor species, the monitoring project has continued after the federal de-listing of the Peregrine. Tens of thousands of raptors have been banded over more than 20 years. A significant number of birds have been recovered throughout the western hemisphere, adding to our understanding of migration pathways.

### **Objectives**

Our objectives in continuing the project to trap raptors at the Wise Point Station are 1) to monitor trends in the migration of several species of diurnal raptors, 2) to learn more about the natural history of migratory raptors, 3) to add to our understanding of migratory movements and pathways for several species, and 4) to continue to develop an educational program at the Eastern Shore of Virginia NWR.

## METHODS

### Study Area

This ongoing project was conducted within the lower Delmarva Peninsula that forms the northern shoreline near the mouth of the Chesapeake Bay. Raptors were trapped within a single site located just north of the southern extent of the Delmarva Peninsula on the Eastern Shore of Virginia National Wildlife Refuge. The trapping blind is located on a topographic high composed of spoil material. The trapping site below the blind has been cleared of vegetation. Vegetation surrounding the site has been rapidly progressing through secondary succession for several years and is now moving into an early tree stage. Vegetation is dominated by a dense layer of wax myrtle (*Myrica cerifera*) with a canopy forming of loblolly pine (*Pinus taeda*), black cherry (*Prunus serrotina*), and hackberry (*Celtis occidentalis*).

### Trapping

The equipment and trapping approach used during the fall of 2003 was consistent with what has been used at the Wise Point site in previous years with some minor modifications. Four mist nets were used instead of the 5 that have been used in recent years. Mist nets were 60-mm, 10-m x 3-m nets. Three of these nets were arranged in a triangle around the high lure pole and the fourth was positioned along an east-west axis near the northern edge of the cleared site. As in past years, two bow nets were used in conjunction with the high and low lure poles. A third bow net and 3 dho-gaza nets were added in 2003 and placed close to the blind for use in the event that the two main bow nets were already sprung on birds. Lure birds used were Rock Doves, European Starlings, and House Sparrows.

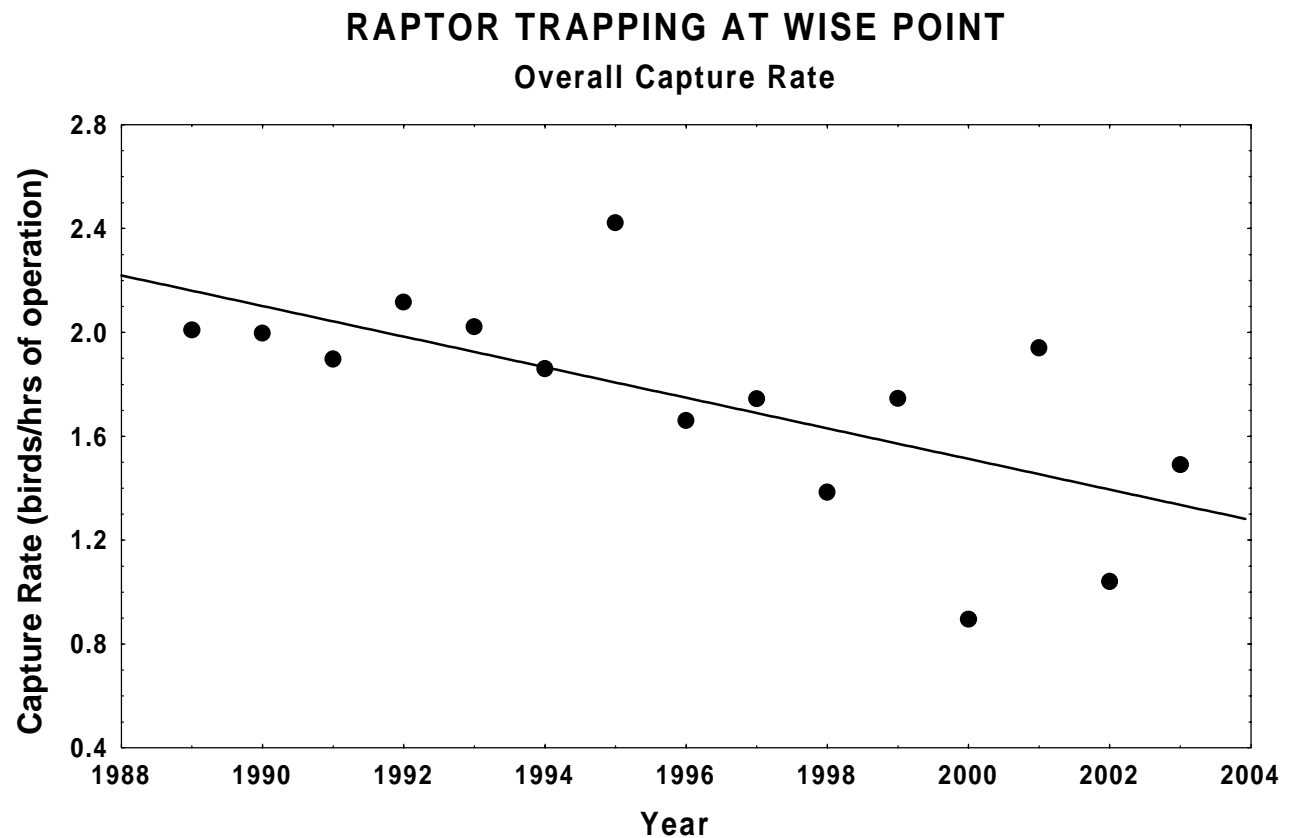

The trapping site was operated on 52 days between 9 September and 23 November, 2003. Resident banders logged a total of 359 hrs of operation. The station was closed for 6 days due to Hurricane Isabel. Nets were generally opened at sunrise and remained open until dark or until raptor activity ceased.

## RESULTS

A total of 516 raptors of seven species (see Appendix I for list of species and Appendix II for banding details) was banded at the Wise Point station during the 2003 fall season. Overall capture rate was 1.4 birds/hr (excluding foreign retraps). The project has recorded lower overall capture rates in only 2 of the previous 15 years. Both of these years were since 1999. The 2003 season continued a downward trend in overall capture rate. Since 1989, capture rate has declined significantly (F-statistic = 9.5, df = 1,13,  $R^2 = 0.42$ ,  $P < 0.01$ ) at an average rate of approximately 6%/year (Figure 1).

**Figure 1.** Trend in overall capture rate between 1989 and 2003 at Wise Point.

The composition of raptor captures in 2003 was consistent with the general pattern recorded in previous years. Accipiter species combined represented 67.8% of overall captures followed by falcons (25.3%). The capture of Cooper's Hawks was the highest over the past 15 years both in terms of the total captures (227) and the capture rate (0.63 birds/hr). The capture of Merlins was the highest since 1999 (Table 1). As in all previous years, late September through October continues to represent the period of heaviest movement for accipiters and falcons (Table 2). Trends in capture rates were not significant (all F-statistics  $< 3.2$ ,  $R^2$ -values  $< 0.2$ , P-values  $> 0.1$ ) over the 15-yr period for all species except Sharp-shinned Hawks. Sharp-shinned Hawks continue to follow a very significant (F-statistic = 43.4, df = 1,13,  $R^2 = 0.77$ ,  $P < 0.001$ ) downward trend with an average rate of

## RAPTOR TRAPPING AT WISE POINT

### Sharp-shinned Hawk Capture Rate

The age distribution of raptors captured in 2003 is generally consistent with that observed in all other years (Table 3). Birds of many species that stop along the lower Delmarva are dominated by young-of-the-year. Mean percentage of hatching-year birds over the past 15 years is  $92.8 \pm 0.828$  for all species combined. During the fall of 2003 overall percentage of hatching-year birds was the lowest during the 15 years at 86.4%.

Six birds that were banded at Wise Point during the 2003 season have been recovered elsewhere. This includes 2 Sharp-shinned Hawks, 3 Cooper's Hawks, and 1 Merlin (see Appendix III for listing of recoveries from the Wise Point station). Recoveries ranged from Dover Delaware to Marathon Florida. The Merlin was banded on the 8<sup>th</sup> of October and recovered in Marathon just 6 days later. A total of 19 birds were captured that had been banded previously elsewhere (see Appendix IV for listing of foreign retraps from Wise Point station). Six of these birds had been banded at Cape May and 7 from Kiptopeke State Park. The remaining birds were from other locations (information requested from banding laboratory).

**Table 3.** Age and sex distribution of raptors capture during 2003 at Wise Point Station. Parenthetic values are percentages.

## DISCUSSION

Results of the fall trapping season of 2003 generally followed the patterns observed on the lower Delmarva Peninsula over the past 20+ years. Migration phenology of the various species and age classes, age ratios, and species composition, were all generally consistent with previous years. Overall capture rate continues to exhibit a significant decline. This decline is apparently driven by the downward trend in captures of Sharp-shinned Hawks. None of the other dominant species show any indication of significant temporal trends.

As with many other raptor species, Sharp-shinned Hawks experienced significant population declines between the 1940's and 1970's in response to environmental contaminants (Snyder et al. 1973). Throughout the 1970's and early 1980's numbers apparently rebounded rapidly in eastern North America (Bednarz et al. 1990). However, migration watch sites reported a second period of decline throughout the 1980's and early 1990's (Kellog 1993, Kerlinger 1992). Reported declines first appeared on the outer coast (Sutton 1988) and later within more inland locations (Laura 1992). The number of Sharp-shinned Hawks migrating along the Delmarva Peninsula appears to have declined since approximately 1980 (Williams, unpubl. data). This observation is consistent with other reports along the mid-Atlantic coast.

Sharp-shinned Hawks breed within forest habitats throughout the northeast. Migrants along both the Atlantic and Appalachian flyways appear to winter primarily in southeastern North America. As with many species, coastal migrants are dominated by hatching-year birds and inland migrants are composed of a comparatively higher ratio of adults. Differences between flyways in both decline rates and age ratios suggest that hatching-year birds may account for a considerable portion of the decline.

The population-level implications of continued declines in capture rates for Sharp-shinned Hawks within the mid-Atlantic remain unclear. A recent investigation by Viverette et al. (1996) that examined trends from both Christmas Bird Counts and mid-Atlantic migration stations shows that wintering birds are increasing north of the mid-Atlantic stations. The study further finds that numbers from migration stations and Christmas Bird Counts north of the mid-Atlantic are inversely correlated suggesting that at least a portion of the reported decline may be due to migration short stopping. It is possible that Sharp-shins are undergoing a northward shift in winter range. Continued long-term monitoring at stations such as Wise Point are essential for documenting and understanding these population-level changes.

## ACKNOWLEDGMENTS

We thank Sue Rice for continued support of this monitoring project. Pam Denmon and other refuge staff provided logistical and other types of support to the project. Eric Slayton, Fletcher Smith and Gabriela Gonzalez provided assistance in operating the site. Tom Olexa provided a supply of pigeons from Langley AFB. Ed Dewars supplied much needed starlings. Reese Lukei, Jr. continues to be a tremendous source of support and expertise for the operation. Financial support for this project was provided by the Virginia Department of Game and Inland Fisheries and the Center for Conservation Biology at the College of William and Mary.
