The proton radius puzzle, the discrepancy between the proton radius measured in muonic hydrogen and electronic hydrogen, has yet to be resolved. There are suggestions that beyond-the-standard-model physics could resolve both this puzzle and the muon anomalous magnetic moment discrepancy. Karshenboim *et al.* point out that simple, nonrenormalizable, models in this direction involving new vector bosons have serious problems when confronting high energy data. The prime example is radiative corrections to $W \rightarrow \mu\nu$ decay which exceed experimental bounds. We show how embedding the model in a larger and arguably renormalizable theory restores gauge invariance of the vector particle interactions and controls the high energy behavior of decay and scattering amplitudes. Thus, beyond-the-standard-model explanations of the proton radius puzzle can still be viable.

I. INTRODUCTION

The 7σ discrepancy between the proton radius measured via the muonic hydrogen Lamb shift [1,2] and measured via electron scattering or electronic hydrogen atomic level splittings (including the Lamb shift in ordinary hydrogen) [3], remains unresolved. Assuming the discrepancy is not due to experimental error, we can consider the explanation that there exists unaccounted for physics which masks itself as a difference in proton size. Such an effect must lower the muonic hydrogen $2S$ state by $310 \mu\text{eV}$ to match experiment. There have been several proposed beyond-the-standard-model (BSM) theories that could explain such an effect. See Refs. [4,5] for reviews.

Furthermore, there exists a discrepancy of 3 or more σ between the measured muonic $g-2$ and that predicted by the standard model [6–9]. A tantalizing hope and goal of these BSM theories is to solve both the proton radius and the muonic $g-2$ problems simultaneously.

One idea in the BSM regime is the existence of a new force that couples preferentially to muons [10–12]. However, a number of constraints must be addressed [13–15]. Many of them can be avoided if we suppose the new force carrier(s) couple(s) only to muons on the leptonic side (or at least much more strongly to muons than to other leptons) and only to first generation particles on the hadronic side, with the hadronic coupling proportional to the electric charge. A neat scheme of this sort has been proposed by Batell *et al.* [11] and further studied by Karshenboim *et al.* [15]. Our own study will be more generic, along the lines of models studied by Rislow and one of the present authors [12]; these models in particular have smaller electron couplings than in Refs. [11,15] and a

different pattern of parity violation such that corrections to the muonium hyperfine splitting and ^{133}Cs weak charge will not arise.

The new muon coupling will affect other processes involving muons, and one immediately thinks of the muon's anomalous magnetic moment, $(g-2)_\mu$, with its circa 2.1 ± 0.7 ppm discrepancy between the standard model and experiment. In the present context, it was early noted [10] that if the mass of the BSM force carrier is very light its effect on $(g-2)_\mu$ can explain the discrepancy directly. If the mass of the new force carrier is not very light, one has to arrange a fine-tuning involving at least one more BSM force carrier to keep the effect of the new physics on $(g-2)_\mu$ at the correct size. This is by now well understood [11,12], and one can even turn it into a positive by solving the $(g-2)_\mu$ problem and the proton radius puzzle with the same model.

Further, if the BSM force carrier is not too heavy, it can contribute as a bremsstrahlung or radiative correction to decays involving muons. For example, the decay $K \rightarrow \mu\nu\phi$, where ϕ is the new force carrier, was studied by Barger *et al.* [14] for the case where ϕ does not visibly decay. If there is a small coupling allowing $\phi \rightarrow e^+e^-$, then the e^+e^- spectrum would show a visible bump above the QED background in $K \rightarrow \mu\nu e^+e^-$, as was considered in Ref. [16].

Karshenboim *et al.* [15] called special attention to the need for embedding any new vector force carrier into a renormalizable theory, or at least into a theory where the scattering or decay amplitudes do not grow with energy when the energy is high. They did this by studying radiative corrections to $W \rightarrow \mu\nu$ decay. The width of this decay is unambiguously predicted in the standard model and is measured with an uncertainty of about 2%. Karshenboim *et al.* showed that if there would be just a low mass vector

 FIG. 1. The illustrative process $\nu_e \bar{\nu}_e \rightarrow W^+ W^-$.

boson that coupled to muons (but not to W 's or ν 's), with a coupling chosen to explain the energy splitting deficit in muonic hydrogen, then its contribution $\Gamma(W \rightarrow \mu\nu V)$ would exceed the measured width of the W by a large margin.

However, in a well-behaved and renormalizable theory, the growth of amplitudes with energy cannot go unchecked. Unitarity imposes limits on the energy behavior of scattering amplitudes, and if one is using the conventions of (say) Bjorken and Drell [17] or of Peskin and Schroeder [18], an amplitude in a single partial wave must not grow with energy at high energy [i.e., if the amplitude grows like $(\text{energy})^n$ for large energies, then $n \leq 0$]. Nonrenormalizable theories are known for their ultraviolet divergences in loops, but their excessive energy dependence can also appear at tree level in the form of unitarity violations. A known historical example is the amplitude for $\nu_e \bar{\nu}_e \rightarrow W^+ W^-$ in a simple vector boson theory [19]. The calculation from Fig. 1(a) gives an amplitude that is asymptotically in a single partial wave that grows like E^2 as the center-of-mass energy $E \rightarrow \infty$. The Weinberg–Salam extension of the theory also has a Z -boson Fig. 1(b), which is significantly smaller than 1(a) at threshold but asymptotically cancels the offending energy behavior and restores perturbative unitarity [20]. A general study by Llewellyn Smith has shown that the need to satisfy unitarity bounds leads to a Yang–Mills structure for many theories involving vector bosons [21].

In this paper, we consider new vector and (when needed) axial-vector bosonic interactions that couple to the muon and the proton but do not couple or couple weakly to the electron and most other particles. Again, if this is all we have, the result of Karshenboim *et al.* shows that the region of parameter space which solves the proton radius problem does not occur in the allowed parameter space given by the known decay of the W . Inspired by Refs. [20,21], we add an additional triple-boson vertex in the Lagrangian, giving an interaction involving the standard W -boson, the new vector particle ϕ_V , and a further vector boson with the same mass as the W . We call this newest boson a “shadow W ,” denoted W_s with $m(W_s) = m_W$. We also include, when needed, a corresponding axial vector triple boson interaction, involving the shadow W_s , the ordinary W , and the ϕ_A . The inclusion of the W_s makes the ϕ interactions gauge invariant or current conserving, arguably fixes the

nonrenormalizability of the original interaction, and, as we shall show, definitively pushes the constraints on the couplings due to W decay far away from the coupling strength parameter region necessary to solve the proton radius problem. Thus, it can be a plausible candidate for a BSM solution to the proton radius problem.

We note that a current conserving theory with massive bosons (ϕ_V and ϕ_A) and shadow W 's gives high energy results, e.g., for radiative corrections to W decay, very much like a theory with a massive scalar boson ϕ_s plus, when needed, a corresponding pseudoscalar boson ϕ_p . We briefly display such a scalar theory and show that decays of the W involving such a scalar and pseudoscalar do not restrict the necessary parameter space needed for solving the proton radius problem with scalar exchanges.

We should also note that, though our theory is well behaved and seems likely to be renormalizable (as argued by Llewellyn Smith [21]), it is not yet a full theory embedded into the standard model (SM). Further work will be required to show how such a theory can be embedded into the SM. For now, we simply consider our theory as a phenomenological application of some BSM physics, containing features that a full theory must contain and controlling the high energy behavior of scattering and decay amplitudes.

In the following, the bulk of our work concerns the new vector or axial vector bosons and is described in Sec. II. We also include some comments on why the corresponding radiative corrections to $Z \rightarrow \mu^+ \mu^-$ decay are innocuous. Results for the scalar case are given in a short Sec. III, and conclusions are offered in Sec. IV.

II. VECTOR THEORY

We start with an interaction Lagrangian similar to Ref. [12] where ϕ_V interacts with a muon (and proton) via the explicit vector coupling C_V^μ (C_V^p) and where ϕ_A interacts with a muon (and proton) through the axial vector coupling C_A^μ (C_A^p). For brevity of notation, it is understood that ϕ without a subscript represents either ϕ_V or ϕ_A in this section. We also include an additional three-boson interaction [21] term involving the ϕ , the ordinary W , and a third boson, with coupling strength equal to C_V^μ (or C_A^μ) as is necessary to make the decay $W \rightarrow \mu\nu\phi$ gauge invariant. The third boson is the shadow W , denoted W_s , which couples to the muon in the same manner as the W and has $m_{W_s} = m_W$.

The new interaction terms in the Lagrangian are

$$\begin{aligned} \mathcal{L}_{\text{int}} = & -\phi_\lambda^V [C_V^\mu \bar{\psi}_\mu \gamma^\lambda \psi_\mu + C_V^p \bar{\psi}_p \gamma^\lambda \psi_p] \\ & -\phi_\lambda^A [C_A^\mu \bar{\psi}_\mu \gamma^\lambda \gamma_5 \psi_\mu + C_A^p \bar{\psi}_p \gamma^\lambda \gamma_5 \psi_p] \\ & -iC_V^\mu \epsilon_{ijk} W_\alpha^i W_\beta^j \partial^\alpha W^{k,\beta} + i\{C_A^\mu \text{terms}\} \\ & -\frac{g}{2\sqrt{2}} \bar{\psi}_\mu \gamma^\lambda (1 - \gamma_5) \psi_\nu W_{s,\lambda}^- + \text{H.c.}, \end{aligned} \quad (1)$$

where in the C_V^μ terms

$$\begin{aligned} W_\alpha^1 &\leftrightarrow W_\alpha^-, \\ W_\alpha^2 &\leftrightarrow W_{s,\alpha}^+, \\ W_\alpha^3 &\leftrightarrow \phi_\alpha^V, \end{aligned} \quad (2)$$

with $V \rightarrow A$ for the C_A^μ terms; ϵ_{ijk} is the totally antisymmetric Levi-Civita symbol. Note that we could use two shadow W 's (one vector and one axial vector) but appear to need only one. Further note the different signs of the C_V^μ and C_A^μ Yang–Mills terms necessary for gauge invariance and that we have included an interaction of the W_s with the charge changing muon current.

If the C_V^μ and C_V^p have the opposite sign, then there exists an additional attractive force between the muon and the proton through the interaction with the ϕ_V . This additional force will create a difference between the $2S$ - $2P$ Lamb shift in muonic hydrogen and hydrogen as [10–12]

$$\Delta E(2S-2P) = -\frac{|C_V^\mu C_V^p|}{4\pi} \frac{m_\phi^2 (m_r \alpha)^3}{2(m_\phi + m_r \alpha)^4}, \quad (3)$$

where m_r is the reduced mass of the (muonic) hydrogen system. The contribution to $\Delta E(2S-2P)$ from the axial coupling C_A^μ is very small.

To account for the energy difference that can be interpreted as a proton radius difference, there must be an extra $310 \mu\text{eV}$ in the $2S$ - $2P$ Lamb shift of muonic hydrogen [1,2]. The parameter C_V necessary to satisfy this constraint is plotted as the green band outlined by solid lines in Fig. 3 where $|C_V^\mu| = |C_V^p| = C_V$.

Furthermore, the introduction of new ϕ_V and ϕ_A interactions with the muon will shift the muon anomalous magnetic moment. The vector and axial vector couplings affect the anomalous moment with opposite signs and can be tuned to account for the known discrepancy between theory and experiment of muonic $g-2$ [12]. If C_V^μ is set to satisfy the proton radius problem, then the allowed region for C_A^μ from the muon $g-2$ constraint is shown by the green band outlined by dashed lines in Fig. 3.

We now move on to consider a constraint emphasized by Karshenboim *et al.* [15], that the branching ratio of $W \rightarrow \mu\nu\phi_V$ plus $W \rightarrow \mu\nu\phi_A$ must be less than 4% (twice the error in the W width as measured by the Tevatron). Without the inclusion of a three-boson interaction, this constraint eliminates the region of the (C_V^μ, m_ϕ) parameter space required to explain the proton radius puzzle. This decay is calculated from the Feynman diagrams given in Fig. 2.

From (1) we can derive the necessary Feynman rules to compute this decay amplitude as

FIG. 2. $W \rightarrow \mu\nu\phi$.

$$\begin{aligned} i\mathcal{M} = & \frac{iC_V^\mu g_W}{2\sqrt{2}} \epsilon_\alpha(k) \epsilon_\beta^*(p_3) \bar{u}(p_1) \left\{ \frac{\gamma^\beta (\not{p}_1 + \not{p}_3)}{(p_1 + p_3)^2} \gamma^\alpha (1 - \gamma^5) \right. \\ & - \gamma^\mu (1 - \gamma^5) \left(\frac{g_{\mu\nu} - \frac{(p_1 + p_2)_\mu (p_1 + p_2)_\nu}{m_W^2}}{(p_1 + p_2)^2 - m_W^2} \right) \\ & \times (g^{\alpha\beta} (k + p_3)^\nu + g^{\beta\nu} (-p_3 + p_1 + p_2)^\alpha \\ & \left. + g^{\alpha\nu} (-p_1 - p_2 - k)^\beta \right\} \nu(p_2), \end{aligned} \quad (4)$$

where k is the W 4-momentum, p_1 is the muon 4-momentum, p_2 is the neutrino 4-momentum, and p_3 is

FIG. 3 (color online). The parameter space necessary to satisfy experimental constraints. Solid lines refer to constraints on C_V^μ . Dashed lines refer to constraints on C_A^μ . The green band, outlined by solid lines, is the constraint on C_V^μ necessary to solve the proton radius problem ($\pm 2\sigma$). The shaded red region, above the line labeled BR ($W \rightarrow \mu\nu\phi$)..., is the forbidden region of C_V^μ due to the constraint that the branching ratio for W goes to $\mu\nu\phi_V + \mu\nu\phi_A$ must be less than 4% under the assumption that C_A^μ solves the muonic $g-2$ problem. The shaded orange region is the restricted region on C_V^μ due to energy splittings in muonic Mg and Si at 2σ . The green band, outlined by dashed lines, is the constraint on C_A^μ necessary to solve the muonic $g-2$ problem ($\pm 2\sigma$) under the assumption C_V^μ solves the proton radius problem ($\pm 2\sigma$).

the ϕ_V 4-momentum. Here we have focused on the vector contribution to the W decay, but one can easily show that the axial vector contribution is equivalent up to an overall minus sign (which is irrelevant to the decay amplitude squared).

Letting the muon and neutrino mass be zero, we find (to leading order in m_ϕ/m_W)

$$\Gamma_W = \frac{G_F m_W^3 [(C_V^\mu)^2 + (C_A^\mu)^2]}{96\sqrt{2}\pi^3} \times \left\{ \log^2 \frac{m_W^2}{m_\phi^2} - 5 \log \frac{m_W^2}{m_\phi^2} + \frac{37}{3} - \frac{\pi^2}{3} \right\}. \quad (5)$$

Keeping the muon mass would only give multiplicative corrections to the coefficients like $(1 + \mathcal{O}(m_\mu^2/m_W^2))$.

This decay width has a strikingly different dependence on m_ϕ compared to Ref. [15]. The $1/m_\phi^2$ dependence found there that came from the longitudinal component of the ϕ polarization is canceled by the inclusion of the W_s propagator in the second diagram of Fig. 2. Thus, at leading order in m_ϕ/m_W , the mass divergence is logarithmic and not inverse polynomial. This logarithmic dependence pushes the constraints from W decay far away from the desired parameter space of C_V^μ and m_ϕ .

The contribution of C_A^μ in (5) can be obtained in terms of C_V^μ using the constraint from $(g-2)_\mu$ [12]. The constraint from W decay eliminates the region of (C_V^μ, m_ϕ) above the top curve, the shaded red area, in Fig. 3. The values of C_V^μ below this area are allowed by this constraint.

Another constraint on C_V^μ occurs from transitions between $3d$ and $2p$ orbitals in muonic ^{24}Mg and ^{28}Si [13,15,22]. At two standard deviations, this constraint is plotted as the shaded orange area bordered below by a solid black line in Fig. 3 where allowed values of C_V^μ exist on and below this line.

Note that an additional constraint due to muonium hyperfine splitting discussed in Ref. [15] is not relevant here since ϕ does not couple to the electron (or the coupling can be kept quite small). For similar reasons, we do not have a constraint on C_A^μ from a new parity nonconserving interaction contributing to the weak charge in ^{133}Cs , significantly opening up the allowed parameter space for (C_A, m_ϕ) .

In Fig. 3 we see that there are broad regions of parameter space for which we can find values of C_V^μ , C_A^μ , and m_ϕ that simultaneously solve the proton radius puzzle and the muonic $g-2$ discrepancy while satisfying the considered experimental constraints.

For completeness, we also comment on radiative corrections to $Z \rightarrow \mu^+\mu^-$ decay, namely $Z \rightarrow \mu^-\mu^+\phi_V$ and $\mu^-\mu^+\phi_A$ decay as represented in Fig. 4.

FIG. 4. $Z \rightarrow \mu^-\mu^+\phi$.

This decay amplitude is

$$i\mathcal{M} = \frac{i}{2} \frac{g_W}{\cos\theta_W} C_V^\mu \epsilon_\alpha(k) \epsilon_\beta^*(p_3) \bar{u}(p_1) \times \left\{ \frac{\gamma^\beta (\not{p}_1 + \not{p}_3)}{(p_1 + p_3)^2} \gamma^\alpha \left(-\frac{1}{2} + 2\sin^2\theta_W - \frac{1}{2}\gamma^5 \right) - \gamma^\alpha \left(-\frac{1}{2} + 2\sin^2\theta_W - \frac{1}{2}\gamma^5 \right) \frac{(\not{p}_2 + \not{p}_3)\gamma^\beta}{(p_2 + p_3)^2} \right\} \nu(p_2), \quad (6)$$

where k is the Z 4-momentum, p_1 is the muon 4-momentum, p_2 is the antimuon 4-momentum, and p_3 is the ϕ_V 4-momentum. As with the W decay, here we only focus on the vector contribution to the Z decay, but one can easily show that the axial vector contribution is equivalent up to an overall minus sign (which is irrelevant to the decay amplitude squared).

In this case, cancellations between the two diagrams ensure the Ward identity is satisfied. Therefore, there is no poor behavior at high energies when the ϕ is longitudinally polarized. This is seen in the logarithmic dependence of the decay width (7) on m_ϕ [which resembles that of the W decay (5)],

$$\Gamma_Z = \frac{G_F m_Z^3 [(C_V^\mu)^2 + (C_A^\mu)^2] [\frac{1}{2} - 2\sin^2(\theta_W) \cos(2\theta_W)]}{48\sqrt{2}\pi^3} \times \left\{ \log^2 \frac{m_Z^2}{m_\phi^2} - 4 \log \frac{m_Z^2}{m_\phi^2} + 5 - \frac{\pi^2}{3} \right\}. \quad (7)$$

As in the calculation of the $W \rightarrow \mu\nu\phi$ decay, we have neglected the muon mass, and we have expanded the Z 's decay width in (7) to leading order in m_ϕ/m_Z . These steps are motivated by the arguments given in the paragraph following (5).

III. SCALAR THEORY

We also consider a scalar theory which is well behaved without the addition of any shadow particles. The interaction Lagrangian is

$$\mathcal{L}_{\text{int},S} = \phi_S [C_S^\mu \bar{\psi}_\mu \psi_\mu + C_S^p \bar{\psi}_p \psi_p] + \phi_P [C_P^\mu \bar{\psi}_\mu \gamma^5 \psi_\mu + C_P^p \bar{\psi}_p \gamma^5 \psi_p], \quad (8)$$

 FIG. 5. $W \rightarrow \mu\nu\phi$.

where ϕ_S is the scalar field, ϕ_P is the pseudoscalar field where $m_{\phi_S} \equiv m_{\phi_P}$, and the C^i 's (with corresponding superscripts and subscripts) are the corresponding coupling strengths. In this section it is understood that ϕ refers to either ϕ_S or ϕ_P .

As with the vector theory, we again consider the constraint due to the branching ratio of $W \rightarrow \mu\nu\phi_S$ plus $W \rightarrow \mu\nu\phi_P$. The decay amplitude for both scalar and pseudoscalar cases is given by the Feynman diagram in Fig. 5.

The result for the decay width is

$$\Gamma_{W,\text{scalar}} = \frac{G_F m_W^3 [(C_S^\mu)^2 + (C_P^\mu)^2]}{96\sqrt{2}\pi^3} \left\{ \log\left(\frac{m_W}{m_\phi}\right) - \frac{17}{12} \right\}, \quad (9)$$

FIG. 6 (color online). The parameter space necessary to satisfy experimental constraints on the scalar coupling C_S^μ . The green band, outlined by solid lines, is the constraint on C_S^μ necessary to solve the proton radius problem ($\pm 2\sigma$). The shaded red region, above the line labeled $\text{BR}(W \rightarrow \mu\nu\phi)$..., is the forbidden region of C_S^μ due to the requirement that the branching ratio for W goes to $\mu\nu\phi_S + \mu\nu\phi_P$ must be less than 4% under the assumption that C_P^μ solves the muonic $g-2$ problem. The shaded orange region is the restricted region on C_S^μ due to energy splittings in muonic Mg and Si at 2σ . The dashed green line is the constraint on C_P^μ necessary to solve both the proton radius and muonic $g-2$ discrepancies (for clarity, only the central value is shown).

where, as with the vector case, we have taken the muon and neutrino mass to be zero.

As with the vector theory, this logarithmic dependence in (9) opens the parameter range in C_S^μ necessary to solve the proton radius problem. This is seen in the constraint plot Fig. 6.

IV. CONCLUSION

We have considered some of the constraints faced by proton radius puzzle explanations that hypothesize a new muon-specific force.

In particular, we have considered some of the necessary features required for a vector mediator to be embedded into a larger renormalizable model. Without the embedding, amplitudes grow quickly with energy, and the energy in W decay is enough to cause trouble. The radiative corrections to $W \rightarrow \mu\nu$ would be larger than the uncertainties in the measured and well-calculated W decay rate, using couplings that could explain the proton radius puzzle. However, with a theory which also contains Yang–Mills couplings, the unphysical energy dependence is ameliorated, and the W width constraint causes no problem for BSM models solving the proton radius puzzle.

The tightest remaining constraint follows from some measured energy splittings in muonic Mg and Si, which are well calculated in the standard model, and new physics cannot cause a deviation larger than the experimental uncertainty. Though this constraint is tight, it does eliminate the muon-specific interaction at the level required for the proton radius problem.

Thus, it is fair to say that a theory involving a new vector (and axial vector) boson, ϕ , along with vector (and axial vector) couplings to the muon and proton, as described by the Lagrangian in Eq. (1), gives a viable representation of the results for some to-be-determined complete solution to the proton radius puzzle. Such a theory necessitates the existence of an additional W -like boson, the shadow W denoted W_s , which fixes the otherwise poor high energy behavior in radiative corrections to $W \rightarrow \mu\nu$ decay first noticed by Karshenboim *et al.* [15].

The arguable success of the vector and axial vector theory, or the scalar and pseudoscalar analog, motivates finding a suitable complete embedding into the Standard Model. Such an embedding must be renormalizable. The addition of a shadow W and corresponding triple-boson interactions is one step in this direction (as pointed out by Llewellyn Smith [21]).

Finding such an embedding may necessitate new interactions which may lead to additional constraints. For example, one must consider the process by which the new bosons acquire their mass. We also expect loop corrections to the self-energy of the W . Corrections with loops of new particles correlate with contributions to the Peskin–Takeuchi parameters [23–25]. Though these

parameters are only defined under certain conditions, e.g., for BSM theories in which new particles are heavy, one can find analogous parameters for theories in which, as in our case, the new boson is light. Contributions to these parameters will be calculated and compared against experimental constraints.

It is also relevant to note that the addition of a new muonic interaction necessitates new radiative corrections beyond just W decay. For example, one may also consider muon decay, pion decay, and the like. Such processes are at a significantly lighter mass scale compared to that of W decay and thus are less likely to cause trouble. We plan to assess if this is true in the near future. Furthermore, changes to the rate of muon pair production from proton collider experiments may provide further constraints on the theory.

These are just some examples of how a vector boson theory may be more restricted than Fig. 3 appears. However, successes so far point to the still possible viability of these theories as solutions to the proton radius (and muonic $g - 2$) puzzle. Thus, continuation of research down this track is well motivated.
