calsequestrin 1 (Casq1) and its fusion constructs to terminal cisternae of the SR, we devised an alternative approach: the fusion of murine Casq1 and D4cpv-a camellion of high dynamic range and affinity adequate for the SR (Palmer, Chem & Bio 2006) - was expressed in the FDB of live adult mice. The fusion protein expressed well, localizing largely to terminal cisternae. Calibrations in situ revealed a good dynamic range of its Ca²⁺-dependent ratio signal (R_{Ca²⁺} = 4). Sensor affinity is being measured using untargeted sensor, expressed in the cytosol, or purified sensor in solution. Assuming a K_d = 240 μM, the resting [Ca²⁺]SR was 0.6-1 mM in 20 cells. Consistent with the kinetics of the related D1 in solution (K_d = 256 ± 1, Palmer, PNAS 2004), D4cpv signals rapidly followed the decrease in [Ca²⁺]SR that results from Ca²⁺ release upon voltage-clamp depolarization. Potential interference by the presence of Casq in the fused sensor was minimized by using a deletion mutant of Casq1 as targeting sequence. A first conclusion is that long-lasting depolarization may reduce [Ca²⁺]SR below 10% of resting value. From the Casq1-D4cpv-monitored [Ca²⁺]SR, we derived the SR Ca buffering power -ratio of total/free [Ca²⁺]SR- and found that it decreases upon depletion of SR Ca. As shown elsewhere (Sztrete et al, this meeting), this anomalous buffering feature depends on the presence of calsequestrin inside the SR. Funded by NIAMS/NIH and MDA.

Ca Depletion and Ablation of Calsequestrin Similarly Increase the Evacuability of the Ca Store of Skeletal Muscle

Allen3, Feliciano Protasi4, Eduardo Rios5, Rush University, Chicago, IL, USA, Université Bordeaux 2, Bordeaux, France, Vanderbilt University, Nashville, TN, USA, Brigham and Women’s Hospital, Boston, MA, USA, 6Cesi-Université d’Annunzio, Chieti, Italy.
At ~200 ms during a voltage pulse the flux of Ca release induced by membrane depolarization of mouse muscle exhibits a characteristic acceleration of decay, or shoulder, associated with SR depletion. The shoulder reflects an increase in evacuation E, an index calculated from the flux, equal to the ratio of release permeability, P, and SR Ca buffering power, B (Royer, J Physiol 2008). To tell whether this rise in E reflects an increase in P or a decrease in B we recorded flux and calculated E in FDB cells from mice lacking either calsequestrin 1 (Palomini, J Physiol 2007) or both isoforms of calsequestrin, the main Ca buffer in the SR. In both null mice the flux waveform lacked the shoulder, and E was elevated, adopting from the start the high value reached upon depletion in the wild-type. Hence, low E requires the presence of calsequestrin inside the store. In aqueous solutions the Ca-binding capacity of calsequestrin decreases at low [Ca²⁺] (Park, JBC 2005). Therefore we hypothesized that the increase in E during a pulse is due to an analogous effect of decaying [Ca²⁺]SR on the Ca-buffering capacity of calsequestrin in situ. Confirming the hypothesis, when the SR was depleted in cells voltage-clamped in zero Ca external solutions, the kinetics of release became similar to that of calsequestrin-null cells, featuring no shoulder and a high initial E. Low evacuability simply implies that the SR may release Ca with minimal decrease in [Ca²⁺]SR, therefore conserving the driving force for subsequent release. A functional correlate is the ability to sustain Ca release and Ca transients during the high frequency activation of physiological contractions and exercise. Funded by NIAMS/NIH and MDA.

Compromised Ca²⁺ Sparks Signaling in the Skeletal Muscle of Diabetic Type 2 Mice

UMDNJ, Piscataway, NJ, USA.
Type 2 diabetes mellitus (DM) is a prevailing epidemic metabolic disease that for effective ([Ca²⁺]SR) signaling may underlie the reduced contractile dysfunction associated with DM. Measurement of osmotic stress induced Ca²⁺ sparks on the young control wild-type (WT)/C57Bl/6J and db/db type 2 DM mice models show that Ca²⁺ sparks frequency is significantly attenuated in the db/db fibers (36 ± 6 events/min) when compared to control (107 ± 7 events/min). These findings suggest that Ca²⁺ sparks can be used as a readout of the Ca²⁺ handling characteristic of skeletal muscle fibers, as we have previously shown in muscular dystrophy and aging muscle. This idea is supported with additional studies that show therapeutic agents for diabetes can modulate Ca²⁺ spark signaling. Treatment of 10 nm glucagon like peptide 1 (GLP1), an incretin hormone associated with increased insulin secretion, significantly increases the Ca²⁺ sparks frequency in the db/db muscle (120 ± 10 events /min), similar to the level of untreated WT. The plot of Ca²⁺ sparks localization shows that treatment of GLP1 in either db/db or WT does not alter the peripheral subcellular normal distribution of Ca²⁺ sparks, implying that the factor responsible for maintaining Ca²⁺ sparks localization near the membrane remains intact. Studies in β-cell suggests that increased specific intracellular signaling cascade can be regulated by GLP-1. We find that these signaling cascades can also contribute to the activation of Ca²⁺ sparks in skeletal muscle.

Local Calcium Signaling

A Technique to Accelerate Stochastic Markov Chain Monte Carlo Simulations of Calcium-Induced Calcium Release in Cardiac Myocytes
George Williams1, Aristide Chikando2, Gregory Smith3, Mohsin Saleet Jafri1, 1George Mason University, Fairfax, VA, USA, 2University of Maryland Biotechnology Institute, Baltimore, MD, USA, 3College of William and Mary, Williamsburg, VA, USA.
Considerable insight into intracellular calcium (Ca) responses has been obtained through the development of whole cell models that are based on molecular mechanisms, e.g., the kinetics of intracellular Ca channels and the feedback of Ca upon these channels. However, a limitation of most deterministic whole cell models to date is the assumption that channels are globally coupled by a "common pool" of [Ca], when in fact channels experience localized "domain" Ca concentrations. More realistic models of Monte Carlo simulations are capable of capturing the influence of local [Ca] on channel gating. Unfortunately, such local control models of calcium-induced calcium release (CICR) are computationally expensive due to the explicit representation of 10,000 to 20,000 release sites, each containing 50 to 300 stochastically gating Ca channels. Here, we present a novel technique called vectorized gating that optimizes the solution time of Markov chain Monte Carlo (MCMC) simulations. Additionally, as this technique leverages vector and matrix algebra it can benefit from the use of the advanced NVIDIA TESLA graphics processing unit (GPU) to further accelerate MCMC models. NVIDIA TESLA cards utilize the parallel nature of the NVIDIA CUDA architecture and are powered by up to 960 parallel processing cores. Benchmark simulations indicate that the GPU-enhanced vectorized gating technique is significantly faster than CPU-only driven calculations. The vectorized gating technique also lends itself to the direct calculation of an adaptive time step which optimizes speed while maintaining numerical stability. These computational enhancements are utilized to facilitate study of sarcolemmal reticulum (SR) leak from clusters of ryanodine receptor (RyR) Ca channels in cardiac myocytes.

In Situ Calibration of Cytoplasmic and Nucleoplasmic Calcium Concentration in Adult Rat and Mouse Cardiac Myocytes
Senka V. Ijubojevic, Stefanie Walther, Burkert M. Pieske, Jens Kocks-Kämper.
Medical Univery of Graz, Graz, Austria. Quantifying subcellularly resolved Ca²⁺ signals in cardiac myocytes is essential for understanding Ca²⁺ fluxes in excitation-contraction and excitation-transcription coupling. Translation of changes in Ca²⁺-dependent fluorescence into changes in [Ca²⁺] relies on the indicator's behavior in situ, but properties of fluorescent indicators in different intracellular compartments may differ. Thus, we determined the in situ calibration of a frequently used Ca²⁺ indicator, Fluo-4, and evaluated its use in reporting cytoplasmic and nucleoplasmic Ca²⁺ signals in isolated cardiac myocytes. Calibration solutions were made by mixing known quantities of EGTA and CaEGTA solutions and the free [Ca²⁺] was confirmed with a Ca²⁺-sensitive electrode. Solutions contained metabolic inhibitors and cyclopiazonic-acid (5μM) to block active Ca²⁺ transport and the Ca²⁺ ionophore A-23187 (10μM) to allow equilibration of [Ca²⁺] between bath solution and cell interior. Ventricular rat and mouse myocytes were loaded with Fluo-4/AM (8μM, 20min). Fluo-4 fluorescence (excitation/emission: 488/505nm) was recorded using a Nipkow dual disc-based confocal microscope. Concentration-response curves were obtained and a significant difference in the apparent Ca²⁺ binding affinities (K_d) of Fluo-4 between cytoplasm (993 ± 68nM; 1026 ± 65nM) and nucleoplasmic (1211 ± 73nM; 1251 ± 71nM) compartments was observed for both rat and cell, respectively (both n=15, P < 0.01). The established curves were used to transform raw Fluo-4 fluorescence signals during electrically stimulated [Ca²⁺] transients.
