(Received 30 August 2011; published 12 November 2012)

An analysis of the pion mass and pion decay constant is performed using mixed-action lattice QCD calculations with domain-wall valence quarks on ensembles of rooted, staggered $N_f = 2 + 1$ configurations generated by the MILC Collaboration. Calculations were performed at two lattice spacings of $b \approx 0.125$ fm and $b \approx 0.09$ fm, at two strange quark masses, multiple light quark masses, and a number of lattice volumes. The ratios of light quark to strange quark masses are in the range $0.1 \leq m_l/m_s \leq 0.6$, while pion masses are in the range $235 \leq m_\pi \leq 680$ MeV. A two-flavor chiral perturbation theory analysis of the lattice QCD calculations constrains the Gasser-Leutwyler coefficients $l_3$ and $l_4$ to be $l_3 = 4.04(40)(^{26}_{63})$ and $l_4 = 4.30(51)(^{64}_{86})$. All systematic effects in the calculations are explored, including those from the finite lattice space-time volume, the finite lattice spacing, and the finite fifth dimension in the domain-wall quark action. A consistency is demonstrated between a chiral perturbation theory analysis at fixed lattice spacing combined with a leading order continuum extrapolation, and the mixed-action chiral perturbation theory analysis which explicitly includes the leading order discretization effects. Chiral corrections to the pion decay constant are found to give $f_\pi/f = 1.062(26)(^{42}_{40})$ where $f$ is the decay constant in the chiral limit, and when combined with the experimental determination of $f_\pi$ results in a value of $f = 122.8(3.0)(^{26}_{63})$ MeV. The most recent scale setting by the MILC Collaboration yields a postdiction of $f_\pi = 128.2(3.6)(^{44}_{53})(^{12}_{64})$ MeV at the physical pion mass. A detailed error analysis indicates that precise calculations at lighter pion masses is the single most important systematic to address to improve upon the present work.

I. INTRODUCTION

The masses and decay constants of the pseudo-Goldstone bosons are hadronic observables that lattice QCD can now calculate with percent-level accuracy in the absence of isospin breaking and electromagnetism. This is primarily due to the fact that the signal-to-noise ratio of the ground state contribution to pion correlation functions does not degrade exponentially with time. While lattice QCD calculations are still being carried out at unphysically large quark masses, with relatively coarse lattice spacings, and in modest volumes, chiral perturbation theory (χPT) can be used to describe the dependence of the pseudo-Goldstone boson masses and decay constants on these variables. Such a description involves a set of low-energy constants (LECs), which can be determined from experimental measurements, or from the lattice QCD calculations themselves. The LECs that are extracted from the pseudo-Goldstone boson observables also appear in other physical processes, and therefore accurate lattice QCD calculations of pion and kaon correlation functions are beginning to translate into predictive power for other—more complicated—observables involving pions and kaons.

χPT, the low-energy effective field theory (EFT) of QCD, provides a systematic description of low-energy processes involving the pseudo-Goldstone bosons [1]. The theory consists of an infinite series of operators (and their coefficients, the LECs) whose forms are constrained by the global symmetries of QCD. The quantitative relevance of these operators is dictated by an expansion in terms of the pion momentum and light quark masses.
suppressed by the chiral symmetry breaking scale, \( \Lambda_\chi \).
At leading order (LO) in the two-flavor \( (n_f = 2) \) chiral expansion, the two coefficients that appear are determined by the pion mass, \( m_\pi \), and the pion decay constant, \( f_\pi \). At next-to-leading order (NLO), there are four new operators in the isospin limit whose coefficients are not constrained by global symmetries [2]; these LECs are the Gasser-Leutwyler coefficients. Two of these LECs, \( \tilde{I}_3 \) and \( \tilde{I}_2 \), can be reliably determined from low-energy \( \pi\pi \) scattering [3]. The LEC \( \tilde{I}_3 \) governs the size of the NLO contributions to \( m_\pi \), while \( \tilde{I}_4 \) controls the size of the NLO contributions to \( f_\pi \). Lattice QCD, the numerical solution of QCD, provides a way to constrain these coefficients, including those that depend upon the light quark masses. Further, as lattice QCD calculations can be performed to arbitrary precision with appropriate computational resources, they will likely provide more precise determinations of the LECs than can be extracted from experimental data. A number of lattice collaborations have recently determined \( \tilde{I}_3 \) and \( \tilde{I}_4 \) using \( n_f = 2 \), \( n_f = 2 + 1 \) and \( n_f = 2 + 1 + 1 \) calculations of \( m_\pi \) and \( f_\pi \) with a variety of lattice discretizations [4–11]. These efforts have been compiled into a review article [12] which has performed averages of these various computational efforts. It should be noted that there is an increasing number of lattice QCD calculations performed at or near the physical point [6,13–16], and it will be exciting to have reliable predictions of hadronic observables that do not rely on \( \chi \)PT.

In this work, we focus on the determination of \( \tilde{I}_3 \) and \( \tilde{I}_4 \) from the pion mass and the pion decay constant using a mixed-action (MA) calculation with domain-wall valence quarks on gauge-field configurations generated with rooted, staggered sea quarks. This serves to strengthen the case that the systematic effects arising from the finite lattice spacing, which are unique to a given lattice discretization, can be systematically eliminated to produce results that are independent of the fermion and gauge lattice actions. There are already preliminary results from mixed-action calculations which can be found in Ref. [17].

Section II describes the details of the lattice QCD calculation. In Sec. III, details of the systematic uncertainties are presented. Continuum and chiral extrapolations of the results of the lattice QCD calculations are detailed in Sec. IV. Conclusions are presented in Sec. V.

II. DETAILS OF THE LATTICE CALCULATION AND NUMERICAL DATA

The present work is part of a program of mixed-action lattice QCD calculations performed by the NPLQCD Collaboration [18–32]. The strategy, initiated by the LHPC Collaboration [33–38], is to compute domain-wall fermion [39–43] propagators generated on the \( n_f = 2 + 1 \) asqtad-improved [44,45] rooted, staggered sea-quark configurations generated by the MILC Collaboration [46,47] (with hypercubic-smeared [48–51] gauge links to improve the chiral symmetry properties of the domain-wall propagators). The predominant reason for the success of this program is the good chiral symmetry properties of the domain-wall action, which significantly suppresses chiral symmetry breaking from the staggered sea fermions and discretization effects [52–54]. This particular mixed-action approach has been used to perform a detailed study of the meson and baryon spectrum [37] including a comparison with predictions from the large-\( N_c \) limit of QCD and \( SU(3) \) chiral symmetry [55,56]. The static and charmed baryon spectrum were, respectively, determined in Refs. [57,58]; the first calculation of the hyperon axial charges was performed in Ref. [59]; the first calculation of the strong isospin breaking contribution to the neutron-proton mass difference was calculated in Ref. [21], and the hyperon electromagnetic form factors were explored in Ref. [60]. The majority of calculations using this mixed-action strategy have been performed at only one lattice spacing, the coarse lattice spacing of \( b = 0.125 \) fm; a notable exception was the calculation of \( B_K \) [61], which included the fine MILC ensembles with \( b = 0.09 \) fm. In Ref. [62], very nice agreement was found between the prediction of the scalar \( a_0 \) correlation function from mixed-action \( \chi \)PT (MA\( \chi \)PT) and the lattice QCD calculations of the same correlation function [63]. This was an important check of the understanding of unitarity violations that are inherent in mixed-action calculations.

A. Lattice QCD parameters

In our previous works [18–32], on the \( b = 0.125 \) fm ensembles, domain-wall valence propagators were calculated on half the time extent of the MILC lattices by using a Dirichlet boundary condition (BC) in the time direction. With the relatively high statistics that have now been accumulated, systematic effects from the light states reflecting off the Dirichlet wall are observed and are found to contaminate the correlation functions in the region of interest (see Fig. 1). This “lattice chopping” strategy has been discarded, and the valence propagators are now calculated with antiperiodic temporal BCs imposed at the end of the full time extent of each configuration. The exception is on the heaviest light quark mass point of the \( b = 0.125 \) fm ensemble. At this heavy pion mass, the correlation function falls sufficiently rapidly to not be significantly impacted in the region of interest by the choice of BC. Further, this ensemble contributes very little to our analysis in Sec. IV.

The parameters used in the present set of lattice QCD calculations are presented in Table I. On the \( b = 0.125 \) fm configurations, light quark propagators computed by LHPC with antiperiodic temporal BCs are used for the three lightest ensembles [38]. Strange quark propagators are computed from the same source points in order to "match" the light quark propagators. In addition, calculations on the \( b = 0.125 \) fm ensembles with a lighter than

physical strange quark mass have been performed. Statistics on three $b = 0.09$ fm ensembles have been accumulated, with the lightest pion mass being $m_\pi = 235$ MeV. Finally, approximately 6500 thermalized trajectories have been completed on an additional rooted staggered ensemble with the parameters 

$$\beta = 6.76, \quad bm_{l_{\text{sea}}}^{\text{res}} = 0.007, \quad bm_{s_{\text{sea}}}^{\text{res}} = 0.050,$$

and measurements have been performed on them.

### B. Results of the lattice QCD calculations

Correlation functions with the quantum numbers of the $\pi^+$ were constructed from propagators generated from a gauge-invariant Gaussian-smeared source \[64, 65\] with both smeared (SS) and point (SP) sinks. To determine the pion mass, the correlation functions were fit with a single \(\cosh\) toward the center of the time direction.

$$C_X(t) \sim A_X e^{-m_\pi t/2} \cosh(m_\pi(t-T/2)), \quad (2)$$

where $X = S, P$. Fits incorporating excited states over larger time ranges produced consistent results for both $m_\pi$ and $A_X$. With domain-wall fermions, the pion decay constant can be computed without need for operator renormalization by making use of an axial ward identity \[66\]. The decay constant is determined from the extracted overlap factors, $A_X$, along with the input quark masses and computed values of the pion mass and residual mass, using the relation

$$b f_\pi = \frac{A_{SP} \sqrt{2(bm_{l_{\text{res}}} + bm_{s_{\text{res}}})}}{(bm_\pi)^{3/2}}. \quad (3)$$

## Table II. The pion masses and decay constants from the lattice QCD calculations. The first uncertainty is statistical and the second is systematic determined from the fit range.

</table>
In the limit $L_5 \to \infty$, the residual chiral symmetry breaking in the domain-wall action vanishes and $m^{\text{res}} \to 0$. In addition to these valence quantities, the mixed valence-sea pion correlation functions have been calculated to extract the mixed-meson masses, as described in Ref. [67].

The results of the lattice QCD calculations are given in Table II. Statistical uncertainties are determined from a correlated $\chi^2$ analysis as well as from a single-elimination jackknife. Binning of the data was performed until the uncertainties did not change appreciably. The quoted fitting systematic uncertainties are determined by varying the fit range, including a broad sweep of $t_{\text{min}}$. Effective mass plots (EMPs) for the full-volume correlation functions are generated with a $\cosh$-style effective mass;

$$m_{\text{eff}}^{(4)} = \frac{1}{\tau} \cosh^{-1}\left[ \frac{C(t + \tau) + C(t - \tau)}{2C(t)} \right],$$

while the others were generated with a log-style effective mass;

$$m_{\text{eff}}^{(5)} = \frac{1}{\tau} \ln\left( \frac{C(t)}{C(t + \tau)} \right).$$

In Figs. 1–3 the EMPs of the correlation functions and the extracted pion masses are presented using $\tau = 3$.

In Fig. 1, the effective masses from calculations with antiperiodic BCs imposed on the valence quarks, as well as those from the Dirichlet temporal BCs, are shown. Correlation functions from propagators generated with a Dirichlet BC (located at $t = 22$ and $t = -10$ in the figures) show a significantly different behavior from those generated with antiperiodic BCs. It is for this reason that we have abandoned the Dirichlet BC in the generation of valence quarks. However, it is only the lightest ensemble on which the extracted pion mass determined with the Dirichlet BC is statistically discrepant from that generated with antiperiodic BCs.

Interestingly, the correlation functions generated with antiperiodic BCs are not free of their own systematics. The EMPs exhibit an oscillation with a period of approximately 1 fm, which is not simply explained by either the staggered taste-pion mass splittings or by the mixed-meson mass splittings. In the top panel of Fig. 2, the oscillations are more pronounced (with higher statistics). Comparing the EMPs from the $b = 0.09$ fm and $b = 0.125$ fm ensembles, the oscillations are seen to become more pronounced for lighter quark masses. As the statistics are increased, the amplitude of the oscillation becomes more significant and increasing $L_5$ does not appear to ameliorate these effects. The choice of $\tau$ used in Eq. (4) has no appreciable impact on the observed oscillation, unless one takes $\tau \approx T_{\text{osc}}$, the oscillation period, in which case the oscillations are washed out. At this point, it is not clear if the oscillations
are an artifact of this particular mixed action or originate from the domain-wall valence propagators. Similar oscillations are observed for calculations with domain-wall valence propagators computed on dynamical domain-wall ensembles, as shown in Fig. 11 of Ref. [9] and Fig. 2 of Ref. [68]. In Ref. [69], it was suggested that these fluctuations may be explained by the time correlations in the propagators. However, in Refs. [70–73], a calculation of

The pion correlation function was performed with \( \sim 400 \) times the number of measurements analyzed in Ref. [69], and no evidence for such oscillations or fluctuations was found (see Figs. 17 and 18 of Ref. [73]). For the present work, the masses and decay constants are determined with fits that encompass at least one full period of oscillation, with the fitting systematic established through variations of the fitting ranges.

### C. Scale setting

To extrapolate the calculated pion masses and decay constants and make predictions at the physical pion mass, the scale must be determined. The MILC Collaboration has performed extensive scale setting analyses on their ensembles, and it is used to convert the calculated pion masses and decay constants into \( r_1 \) units (extrapolated to the physical values of the light quark masses),\(^1\) collected in Table III. In Table IV these values are listed for the ensembles used in this work [47]. The MILC Collaboration has determined \( r_1 = 0.318(7) \) fm using the \( b \bar{b} \) meson spectrum and \( r_1 = 0.311(2)(3) \) fm using \( f_\pi \) to set the scale [47]. The value of

\[
r_1 = 0.311(2)(3) \ 	ext{fm}
\]

is used in this work to convert to physical units.

### III. LATTICE SYSTEMATICS

In order to make contact with experimental measurements, the lattice QCD results must be extrapolated to the continuum and to infinite volume, as well as to the physical values of the light quark masses. \( \chi PT \) is the natural tool to perform these extrapolations, a consequence of which is that the LECs can be determined.

#### A. Light quark mass and volume dependence

Generally, the chiral expansion at NLO involves analytic terms, chiral logarithms and scale-dependent LECs. However, the perturbative expansion can be optimized by setting the renormalization scale to lattice-determined quantities which vary with the quark mass, leading to modifications at next-to-next-to-leading order (NNLO). For instance, the \( SU(2) \) chiral expansion of \( m_\pi \) and \( f_\pi \) can be expressed as [12,18]

\[
m_\pi^2 = 2B m_q \left\{ 1 + \frac{1}{2} \xi \ln \left( \frac{\xi}{\xi_{\text{phy}}} \right) - \frac{1}{2} \xi \tilde{t}_3 \right\},
\]

\[
f_\pi = f \left\{ 1 - \xi \ln \left( \frac{\xi}{\xi_{\text{phy}}} \right) + \xi \tilde{t}_4 \right\},
\]

where

---

\(^1\)The distance \( r_1 \) is the Sommer scale [74] defined from the heavy-quark potential at the separation, \( r_1^2 F(r_1) = -1 \).
\[ \xi = \frac{m_{\pi}^2}{8\pi^2 f_{\pi}^2} \quad \text{and} \quad \tilde{I}_i = \log \left( \frac{\Lambda_i^2}{(m_{\text{phy}}^\pi)^2} \right), \]

and \( \Lambda_i \) is an intrinsic scale that is not determined by chiral symmetry. Here \( m_{\pi} \) and \( f_{\pi} \) denote lattice-measured quantities, \( f \) is the chiral-limit value of the pion decay constant, and \( B \) is proportional to the chiral condensate. The “phy” superscript indicates that the relevant quantity is evaluated with the physical values of the pion mass and decay constant, for which we use the central values

\[ f_{\pi}^{\text{phy}} = 130.4 \text{ MeV} \quad \text{and} \quad m_{\pi}^{\text{phy}} = 139.6 \text{ MeV}. \]

One benefit of performing the perturbative expansion with \( \xi \) is immediately clear: as \( \xi \) is dimensionless, the higher order corrections are free of scale setting ambiguities as only the physical quantities are used.

In addition to the light quark mass dependence, the finite-volume corrections to the pion masses and decay constants can be simply expressed in the \( p \) regime, defined by \( m_{\pi} L \gg 1 \). At NLO in the chiral expansion, the finite-volume corrections are given by \([75,76]\)

\[
\Delta^{(\text{FV})} \frac{m_{\pi}^2}{2Bm_q} = 8\pi^2 \Delta iI(\xi, m_{\pi} L),
\]

where

\[ 8\pi^2 \Delta iI(\xi, m_{\pi} L) = 2\frac{\xi}{m_{\pi} L} \sum_{n=1}^{\infty} \frac{k(n)}{\sqrt{n}} K_1(\sqrt{nm_{\pi} L}) \]

and \( k(n) \) is the number of ways that the integer \( n \) can be formed as the sum of squares of three integers, \( n = \sum_{i=1}^{3} n_i^2 \).

The light quark mass dependences of \( m_{\pi} \) and \( f_{\pi} \) are known at NNLO in two-flavor \( \chi PT \) \([77]\). In the \( \xi \) expansion, in infinite volume, they are

\[
\frac{m_{\pi}^2}{2Bm_q} = 1 + \frac{1}{2} \xi \left[ \ln \left( \frac{\xi}{\xi_{\text{phy}}} \right) - \tilde{I}_3 \right] + \frac{7}{8} \xi^2 \ln^2(\xi)
- \left[ \frac{16}{3} + \frac{1}{3} \tilde{I}_{12} - \frac{9}{4} \tilde{I}_4 - \frac{7}{4} \ln(\xi_{\text{phy}}) \right] \xi^2 \ln(\xi)
- \tilde{I}_4 \xi_{\text{phy}} + \xi^2 k_M
\]

and

\[
\frac{f_{\pi}}{f} = 1 + \xi \left[ \tilde{I}_4 - \ln \left( \frac{\xi}{\xi_{\text{phy}}} \right) \right] + \frac{5}{4} \xi^2 \ln^2(\xi)
+ \xi^2 \ln(\xi) \left[ \frac{53}{12} + \frac{1}{6} \tilde{I}_{12} - \frac{5}{4} \tilde{I}_4 - \frac{7}{2} \ln(\xi_{\text{phy}}) \right]
+ 2\tilde{I}_4 \xi_{\text{phy}} + \xi^2 k_F,
\]

where \( \tilde{I}_{12} = 7\tilde{I}_1 + 8\tilde{I}_2 \).

### B. Mixed-action \( \chi PT \)

The low-energy EFT for mixed-action lattice QCD calculations is well understood \([52–54,62,63,67,78–85]\). In Refs. \([53,54,85]\), it was demonstrated that the formulas for the pion mass and decay constant at NLO, including discretization effects, are the same for all sea-quark discretizations provided the valence quarks satisfy the Ginsparg-Wilson relation \([86]\) (including our MA approach with domain-wall valence propagators computed on rooted staggered sea-quark configurations). The difference between the various sea-quark actions will be encoded in the values of the unphysical parameters which quantify the discretization effects. At NLO in the MA expansion, including finite-volume effects, the pion mass and decay constant are given by

\[
\frac{m_{\pi}^2}{2Bm_q} = 1 + \frac{1}{2} \xi \ln \frac{\xi}{\xi_{\text{phy}}} - \frac{1}{2} \xi \tilde{I}_3
- \frac{1}{2} (\xi_{\text{sea}} - \xi) \left[ 1 + \ln(\xi) \right] - \tilde{I}_{3}^{\text{QO}} (\xi_{\text{sea}} - \xi)
+ \tilde{I}_4^{\text{QO}} (\xi_{\text{sea}} - \xi) \Delta \tilde{i} I(m_{\pi} L),
\]

where

\[
\Delta \tilde{i} I(m L) = \frac{1}{(4\pi)^2} \sum_{n=1}^{\infty} k(n) \left( K_0(\sqrt{n}m L) + K_2(\sqrt{n}m L) - 2K_1(\sqrt{n}m L) \right).
\]

For the present calculations, the extra expansion parameters of the theory are defined as

\[
\tilde{\xi}_{\text{Mix}} = \frac{1}{4}(m_{\pi}^2 + m_{\pi_{\text{sea}}}) + b^2 \Delta_{\text{Mix}}^l,
\]

\[
\tilde{\xi}_{\text{sea}} = \frac{m_{\pi_{\text{sea}}}^2}{8\pi^2 f_{\pi}^2} + \frac{b^2 \Delta_{\text{Mix}}^l}{8\pi^2 f_{\pi}^2},
\]

where \( m_{\pi_{\text{sea}}} \) is the taste-5 staggered pion mass, \( b^2 \Delta_{\text{Mix}}^l \) is the mass splitting of the taste identity staggered pion and \( b^2 \Delta_{\text{Mix}}^\pi \) is the mass splitting of the mixed valence-sea pion \([80,85]\), determined in Refs. \([62,67]\) and this work. In Table V, the values of the parameters relevant for the calculations are listed.

In analogy with finite-volume \( \chi PT \), the pion mass and pion decay constant in finite-volume MA \( \chi PT \) are related to their infinite-volume values at NLO via the relations
In the case of $f_\pi$, the finite-volume effects in MA$\chi$PT are somewhat suppressed compared to those in $\chi$PT. This is because the contribution from the “average” valence-sea-type virtual pion in a one-loop diagram is smaller than from a valence-valence pion due to its larger mass [67]. In contrast, the pion mass receives a one-loop contribution from a hairpin diagram [87], which has enhanced volume effects compared to a typical one-loop contribution. In Table VI, the FV contributions to $m_\pi$ and $f_\pi$ from Eqs. (20) and (21) are presented. On the lightest two coarse ensembles, the NLO volume contributions to $m_\pi$ from MA$\chi$PT are substantially larger than those from $\chi$PT. Further, due to the high precision of the lattice QCD calculations, the finite-volume contributions are larger than the uncertainties on the m007m050 ensembles. This is in contrast to the results of the lattice QCD calculations of $m_\pi$, which show little volume dependence. In Ref. [88], it was demonstrated that NNLO $\chi$PT could increase the finite-volume contributions by as much as $\sim$50% of the NLO contribution. In the case of MA$\chi$PT, with hairpin diagrams having enhanced volume effects, the importance of the NNLO contributions is likely to be even greater than in $\chi$PT. As these NNLO effects have not yet been calculated, the MA$\chi$PT finite-volume contributions are assigned a 30% systematic uncertainty when performing the analysis in Sec. IV. In Fig. 4, the NLO finite-volume contributions in $\chi$PT and in MA$\chi$PT for the m007m050 and m010m050 ensembles are compared with the results of the lattice QCD calculations. The $\chi$PT band is given by the range $\Delta m_\pi = (1 + 0.5)\Delta m_\pi^{\text{PT}}$, while the MA$\chi$PT

corrections are given by $\Delta m_{\pi} = (1 \pm 0.3) \Delta m_{\pi}^{\text{MA} \chi \text{PT}}$, where the central values have been chosen to coincide for the larger volume ensembles. The MA$\chi$PT finite-volume contributions appear to not describe the observed volume dependence of $m_{\pi}$, indicating the likely importance of NNLO contributions. In the case of $f_{\pi}$, the volume contributions are in good agreement with the results of the lattice QCD calculations.

C. Strange quark mass effects

The strange quark masses used in the present calculations are not equal to the physical value [89]; the physical staggered strange quark mass was determined to be $b m_{s}^{\text{phy}} = 0.0350(7)$ and $b m_{s}^{\text{phy}} = 0.0261(5)$ on the $b = 0.125$ fm and $b = 0.09$ fm ensembles, respectively [47]. In order to estimate the effects of this small mistuning in the two-flavor expansion, a matching to $SU(3)$ $\chi$PT must be performed, where it is found the effects can be absorbed into the NLO LECs [90]:

$$\tilde{I}_3(m_s, m_{s}^{\text{phy}}) = \tilde{I}_3(m_{s}^{\text{phy}}) + \delta \tilde{I}_3(m_s, m_{s}^{\text{phy}}),$$

$$\delta \tilde{I}_3(m_s, m_{s}^{\text{phy}}) = -\frac{1}{9} \ln \left( \frac{m_s}{m_{s}^{\text{phy}}} \right).$$

$$\tilde{I}_4(m_s, m_{s}^{\text{phy}}) = \tilde{I}_4(m_{s}^{\text{phy}}) + \delta \tilde{I}_4(m_s, m_{s}^{\text{phy}}),$$

$$\delta \tilde{I}_4(m_s, m_{s}^{\text{phy}}) = \frac{1}{4} \ln \left( \frac{m_s}{m_{s}^{\text{phy}}} \right).$$

These lead to mild corrections to $\tilde{I}_3$ and $\tilde{I}_4$ on both the coarse and fine ensembles,

$$\delta \tilde{I}_3(m_s, m_{s}^{\text{phy}}) = \begin{cases} -0.040(2), & b = 0.125 \text{ fm}, b m_{s}^{\text{sea}} = 0.05 \\ -0.019(1), & b = 0.09 \text{ fm}, b m_{s}^{\text{sea}} = 0.031 \end{cases};$$

$$\delta \tilde{I}_4(m_s, m_{s}^{\text{phy}}) = \begin{cases} 0.089(5), & b = 0.125 \text{ fm}, b m_{s}^{\text{sea}} = 0.05 \\ 0.043(5), & b = 0.09 \text{ fm}, b m_{s}^{\text{sea}} = 0.031. \end{cases}$$

These strange quark-mass mistuning effects are negligible compared with the uncertainties of the extracted values for $\tilde{I}_3$ and $\tilde{I}_4$ (see Sec. IV).
TABLE VII. Parameters used to isolate \( m^\text{res} \) effects. The \( L_5 = 16, 24 \) calculations were used to tune the quark mass for the \( L_5 = 40 \) calculation in such a way that the sum \( b(m_i + m^\text{res}_i) \) was the same (within \( \sim 0.7\% \)) for the \( L_5 = 12 \) and 40 calculations.

\[
\begin{array}{cccccc}
\text{Ensemble} & L_5 & b m_l & b m^\text{res} & \frac{m^\text{res}_i}{m_i + m^\text{res}_i} & b m_\pi & b f_\pi \\

& 40 & 0.0038 & 0.000156(03) & 0.039(1) & 0.10328(32)(^{+6}_{-10}) & 0.0621(09)(^{+10}_{-13}) \\
\end{array}
\]

D. Residual chiral symmetry breaking effects

The domain-wall action has residual chiral symmetry breaking due to the finite extent of the fifth dimension, \( L_5 \), resulting from the overlap of the chiral modes bound to opposite walls in the fifth dimension. The quantity \( m^\text{res} \) is the leading manifestation of this residual chiral symmetry breaking, and the effective quark mass of the lattice QCD calculation becomes

\[
m_q = m^\text{unf}_q + m^\text{res}_q, \tag{24}
\]
capturing the dominant effects of the residual chiral symmetry breaking appearing at LO in the chiral Lagrangian. However, it is known that there are subleading effects. Defining the quark mass through Eq. (24) and taking the standard definition of \( m^\text{res} \) as the ratio of two pion to vacuum matrix elements [66]

\[
b m^\text{res} = \frac{\langle 0| J_{q \mu}^u | \pi \rangle}{\langle 0| J_{q \mu}^s | \pi \rangle}, \tag{25}
\]
where \( J_{q \mu}^u \) and \( J_{q \mu}^s \) are pseudoscalar densities made, respectively, from quarks in the middle and boundaries of the fifth dimension, the quantity \( m^\text{res} = m^\text{res}(b m_q, b) \) depends upon the input quark mass and the lattice spacing (see Ref. [9] for a discussion of these effects). Consequently, the chiral Lagrangian receives a simple modification at NLO [91–93]. Following the method of Ref. [94], the modifications to the chiral Lagrangian at NLO are

\[
\delta L_{\text{res}} = \frac{1}{16} \left( \frac{b m_q}{m} \right)^2 \left( \text{tr}(2 B m_q \Sigma + 2 B m_q \Sigma^\dagger) \times \text{tr}(2 B m^\text{res}_q \Sigma + 2 B m^\text{res}_q \Sigma^\dagger) + \frac{1}{8} \left( \partial_{\mu} \Sigma \partial^{\mu} \Sigma^\dagger \right) \text{tr}(2 B m^\text{res}_q \Sigma + 2 B m^\text{res}_q \Sigma^\dagger). \right.
\]

The corrections to \( m_\pi \) and \( f_\pi \) arising from these new terms are

\[
\frac{\delta m^2_\pi}{2 B m_q} = -\frac{1}{2} \xi \frac{m^\text{res}_q}{m_q} \tilde{r}^\text{res}_{\xi} \quad \text{and} \quad \frac{\delta f_\pi}{f} = \xi \frac{m^\text{res}_q}{m_q} \tilde{r}^\text{res}_{\xi}, \tag{27}
\]
with

\[
\tilde{r}^\text{res}_{\xi} = \frac{32 \pi^2}{\gamma_\xi} \tilde{r}^\text{res}_{\xi}, \tag{28}
\]
where \( \gamma_3 = -1/2 \) and \( \gamma_4 = 2 \) [2]. As with the coefficients \( \tilde{r}^\text{res}_i \), these \( \tilde{r}^\text{res}_i \) coefficients are not universal and depend upon the choice of lattice action used.

The new operators in Eq. (26) were found to give the dominant uncertainty in the prediction of the \( I = 2 \pi \pi \) scattering length at the physical pion mass [25] as the \( r^\text{res}_i \) were unknown. Therefore, for \( \pi \pi \) scattering, and for other observables, it is important to determine the \( r^\text{res}_i \), which can be done simply by performing calculations with different values of \( L_5 \) on the same ensemble. The fine MILC ensembles, with \( b = 0.09 \text{ fm} \), at the lightest quark-mass point were used to perform calculations with \( L_5 = 12 \) and \( L_5 = 40 \). The quark mass, defined by Eq. (24), was tuned to be the same for both \( L_5 \)'s, which was achieved to within 0.7% accuracy (giving the same value of \( m^2_\pi \) up to \( \sim 3\% \)). The results of the calculations are presented in Table VII. The values of \( r^\text{res}_i \) and \( r^\text{res}_i \) that are determined by the lattice QCD calculations are presented in Sec. IV.

IV. CHIRAL, CONTINUUM AND VOLUME EXTRAPOLATIONS

The numerical results presented in this work were obtained at several values of the light quark masses and two lattice spacings. To control the discretization effects, it would be ideal to have at least three lattice spacings; however, a third smaller lattice spacing is beyond the scope of this work. To address this limitation, the chiral and continuum extrapolations are performed in two different ways. The first method is to fit the LECs of \( \chi \text{PT} \) to the \( b = 0.125 \text{ fm} \) and \( b = 0.09 \text{ fm} \) calculations independently. The extracted LECs are then extrapolated to the continuum limit, using the ansatz

\[
\lambda(b) = \lambda_0 + \lambda_2 \left( \frac{b}{r_1} \right)^2. \tag{29}
\]
This analysis is performed at both NLO and NNLO in the chiral expansion. The second method to perform the continuum and chiral extrapolations is to use MA\( \chi \text{PT} \), which leads to determinations of the LECs that are consistent with those obtained with the first method. This lends confidence

\[
094509-11
\]
that the discretization effects are small enough to be captured by the MAχPT formulation.

Before proceeding, it should be noted that the light quark masses are given in lattice units and have not been converted to a continuum regularization scheme. As the product \( m_q B \) is renormalization scheme and scale independent, the values of the LEC B, which we determine, have not been properly converted to a continuum regularization scheme. For this reason, we do not provide the results of this quantity.

A. Method 1: χPT and continuum extrapolation

1. NLO SU(2)

The pion masses and decay constants obtained in the lattice QCD calculations on the \( b = 0.125 \) fm and \( b = 0.09 \) fm ensembles are used to determine the LECs at NLO in χPT by independently fitting to the expressions in Eqs. (7) and (8), including the FV corrections in Eqs. (11) and (12). Strange quark-mass effects are included by using Eq. (22), but residual chiral symmetry breaking effects, such as those described by Eq. (27), are not. Both the mass and decay constant depend upon two LECs each, as seen from Eqs. (7) and (8). The uncertainties in the values of \( \xi \) and other parameters in Table V are included in our analysis through our Monte Carlo treatment but do not appreciably impact the analysis. Including the larger volume calculations, the complete set of results presented in Table III utilizes six data sets on the \( b = 0.125 \) fm ensembles and three on the \( b = 0.09 \) fm ensembles. For each of the NLO fixed lattice-spacing fits that are presented in Tables VIII and IX, the maximum value of \( m_1/m_s \) used in the fit is listed. On the \( b = 0.125 \) fm ensembles, the ratio is in the range \( m_1/m_s = 0.14–0.6 \), while on the \( b = 0.09 \) fm ensembles the ratio is in the range \( m_1/m_s = 0.1–0.4 \).\(^3\)

From the quality of fit given in Tables VIII and IX, it is clear that the NLO χPT formula for \( m_\pi \) fails to describe the results of the lattice QCD calculation at either lattice spacing, while the NLO χPT formula for \( f_\pi \) describes the results on the lightest three \( b = 0.125 \) fm ensembles well and describes all the results on the \( b = 0.09 \) fm ensembles.

\(^3\)In addition to giving the \( \chi^2 \) and the number of degrees of freedom (d.o.f.) in the fit, the \( Q \) value, or confidence of fit, is also provided,

\[
Q = \int_{\chi_{min}}^{\infty} d\chi^2 P(\chi^2, d),
\]

where

\[
P(\chi^2, d) = \frac{1}{2^{d/2}\Gamma(d/2)}(\chi^2)^{d/2-1}e^{-\chi^2/2}
\]

is the probability distribution function for \( \chi^2 \) with \( d \) degrees of freedom. (The \( Q \) value represents the probability that if a random sampling of data were taken from the parent distribution, a larger \( \chi^2 \) would result.)

Taking the results of the fits with \( m_1/m_s \leq 0.4 \), a continuum extrapolation of the extracted LECs using Eq. (29) gives

\[
\tilde{I}_3 = 3.2(0.2)(1.2) \quad \text{and} \quad \tilde{I}_4 = 6.3(0.3)(1.1).
\]

The NLO χPT determination of \( \tilde{I}_3 \) must be taken with extreme caution (and essentially discarded) as the fit to \( m_\pi \) is poor. This (relatively) large value of \( \tilde{I}_4 \) extracted at NLO is consistent with the JLQCD NLO results using \( n_f=2 \) overlap fermions [5].

2. NNLO SU(2)

The pion mass and decay constant at NNLO in χPT, given in Eqs. (14) and (15), depend upon two additional LECs, \( k_M \) and \( k_F \), in addition to the appearance of further NLO LECs \( \tilde{I}_{12} = 7\tilde{I}_1 + 8\tilde{I}_2 \). Both \( \tilde{I}_1 \) and \( \tilde{I}_2 \) are reasonably well determined from \( \pi\pi \) scattering [3],

\[
\tilde{I}_1 = -0.4(6) \quad \text{and} \quad \tilde{I}_2 = 4.3(1).
\]

To perform the fits at NNLO, these values of \( \tilde{I}_1 \) and \( \tilde{I}_2 \) are used as input. Normal distributions of \( \tilde{I}_1 \) and \( \tilde{I}_2 \) are generated with means and variances given by Eq. (33), which are then used in the fitting process. This allows for a determination of the systematic uncertainty generated by their use as input parameters. In fitting to the results of the

\[094509-12\]
calculations on the $b \approx 0.09$ fm ensembles, there are six lattice QCD results, and six fit parameters. The results of this analysis are collected in Table X. The NNLO $\chi$PT is found to describe the results of the lattice QCD calculations for both $m_\pi$ and $f_\pi$. Taking the $b \approx 0.125$ fm and $b = 0.09$ fm fit and using them to perform a continuum extrapolation,

$$\tilde{I}_3 = 3.3(1.4)(1.7) \quad \text{and} \quad \tilde{I}_4 = 5.8(2.4)(3.5) \quad (34)$$

are obtained, consistent with those from the NLO analysis. These results must also be treated with caution due to the small number of calculations performed on the $b \approx 0.09$ fm ensembles. In Figs. 8 and 9, one can see the approximate contribution of discretization effects in the values of $\tilde{I}_3$ and $\tilde{I}_4$.

**B. Method 2: Mixed-action $\chi$PT**

As in the continuum case, the $m_\pi$ and $f_\pi$ analyses with MA$\chi$PT are decoupled at NLO in the expansion, but the results of the lattice QCD calculations at both lattice spacings can be fit simultaneously. This allows for several choices of fit ranges, which are denoted as A–E in Table XI. The maximum value of $m_l/m_s$ used in the fits from the $b = 0.125$ fm and $b = 0.09$ fm ensembles are listed in Table XI. As discussed in Sec. IIIB, the NLO MA$\chi$PT volume contributions are assigned a 30% uncertainty as an estimate of NNLO effects. This additional uncertainty is combined in quadrature with the other quoted systematic uncertainties.

**TABLE XI.** Fit ranges used in the MA$\chi$PT analysis. For a given fit, A–E, the maximum value of $m_l/m_s$ (sea-quark masses) is given.

**1. NLO mixed-action $\chi$PT**

Fits are performed over the ranges listed in Table XI, the results of these analyses are collected in Tables XII and XIII. There are a few observations to make. First, the NLO MA$\chi$PT formula is capable of describing the results of the lattice QCD calculations of $m_\pi$, unlike the NLO $\chi$PT formula. Second, the MA$\chi$PT provides a slightly better description of the pion decay constant than of the pion mass. In both cases, the NLO formula is capable of describing the results of the lattice QCD calculations over the full range of quark masses.

As the $Q$ value has a probabilistic interpretation, it is convenient to use it in forming weighted averages of the quantities that have been extracted with multiple fitting procedures and/or different numbers of degrees of freedom. For extractions of a parameter $\lambda$ from different procedures, each giving $\lambda_i$ with $Q_i$, the weighted average

$$\bar{\lambda} = \frac{\sum_i Q_i \lambda_i}{\sum_j Q_j} \quad (35)$$

can be formed. As each of the fits considered in this work, presented in Table XI, includes successively larger quark masses, this averaging will give more weight to the lighter quark-mass values, where $\chi$PT is more reliable. Performing this $Q$-weighted averaging of the results from Tables XII and XIII gives

$$\bar{\tilde{I}}_3[\text{NLO}] = 4.13(20)(31), \quad \bar{\tilde{I}}_4[\text{NLO}] = 6.09(40)(37),$$

$$\bar{\tilde{I}}_3^{\text{res}}[\text{NLO}] = 18(5)(3), \quad \bar{\tilde{I}}_4^{\text{res}}[\text{NLO}] = 5(11)(1). \quad (36)$$

The value of $\bar{\tilde{I}}_3$ is consistent with the average of all other lattice QCD calculations [12]. However, the value of $\bar{\tilde{I}}_4$ is noticeably higher, but is consistent with that obtained with $N_f = 2$ overlap fermions and a NLO $\chi$PT analysis [5].

While the residual chiral symmetry breaking LECs are not

---

4NPLQCD has consistently performed systematic uncertainty analysis by weighting the results of different but equivalent fitting strategies [18–32]. This particular method of $Q$ weighting has also been advocated by the BMW Collaboration [13], for example.
well determined, they will help constrain the analysis of the $I = 2\pi \pi$ scattering length \[25\].

2. NLO $\chi^3$PT + NNLO $SU(2)$ $\chi$PT

While the complete NNLO expressions for the pion mass and decay constant are not available in $\chi^3$PT, it is useful to consider the hybrid construction of NLO $\chi^3$PT plus NNLO $\chi$PT. As in the previous section, the NLO $\chi^3$PT volume contributions are assigned a 30% uncertainty. Further, the infinite-volume formulas for the NNLO contributions are used. While the fit values of the NNLO LECs will be polluted by discretization effects, the NLO Gasser-Leutwyler coefficients will be free of these contaminations, and further, their extracted values should be stabilized with the inclusion of these higher order contributions.

The fit functions for $m_\pi$ and $f_\pi$ share two LECs; at NNLO, $m_\pi^2$ depends upon $\tilde{l}_4$ as well as $\tilde{l}_3$, and both depend upon $\tilde{l}_{12}$; see Eqs. (14) and (15). In principle, a correlated analysis should be performed; however, the correlations only exist at NNLO, and are expected to be insignificant. To capture the effects of the correlations on the central value of $\tilde{l}_4$, the extrapolation analysis is performed with a Monte Carlo. Further, as seen in Fig. 7, the NNLO contributions to $m_\pi$ are insignificant, supporting the above expectation. In order to verify these expectations, a fully correlated fit was performed on a subset of the fits, A–E. The change in the values of the LECs was well contained within the quoted uncertainties. Results of these fits are presented in Table XIV for the various data sets. Taking the $Q$-weighted average of these results gives

with $\bar{\ell}_3[\text{NNLO}]$ and $\bar{\ell}_4[\text{NNLO}]$ in good agreement with the averages given in Ref. [12]. At NNLO in the chiral expansion, corrections to the pion decay constant are found to be

$$\frac{f_\pi}{f}[\text{NNLO}] = 1.062(26)(^{42}_{40}).$$

(37)

Setting the scale either by using $r_1^\text{phy} = 0.311(2)(^{3}_{8})$ fm from the MILC Collaboration to determine $f_\pi^\text{phy}$, or by using the experimental value of $f_\pi^\text{phy}$ to determine $r_1$, gives

$$f_\pi^\text{phy}[\text{NNLO}] = 128.2(3.6)(^{6}_{4})^{(1.7)}_{(1.3)} \text{ MeV} \quad \text{and} \quad r_1^\text{phy}[\text{NNLO}] = 0.306(9)(^{10}_{14}) \text{ fm},$$

(39)

where the last uncertainty in the postdicted value of $f_\pi$ comes from MILC’s determination of $r_1$, Eq. (6).

Figure 5 shows Monte Carlo histograms of the extracted values of $\bar{\ell}_3$ and $\bar{\ell}_4$ using the $Q$ weights to determine the ratio of samples to draw from each of fits A–E. The result of fit E for $f_\pi$, extrapolated to the infinite volume and continuum limits is displayed in Fig. 6. The inner (colored) band represents the 68% statistical confidence interval while the outer (gray) band results from the 68% statistical and systematic uncertainties combined in quadrature. The dashed vertical line is located at $\xi^\text{phy}$ determined from Eq. (10).

C. Convergence of the $SU(2)$ chiral expansion

With the analyses performed in the previous section in hand, the convergence of the two-flavor chiral expansion can be explored. The resulting NLO and NNLO contributions to the quantities

$$\frac{m_\pi^2}{2Bm_\pi} - 1 \quad \text{and} \quad \frac{f_\pi}{f} - 1$$

(40)

(both of which vanish in the chiral-limit) are shown in Fig. 7. In both cases (the left and right panels of Fig. 7), it is the continuum limit and infinite-volume limit extrapolations that are displayed. In the case of $m_\pi$, the NNLO contributions are negligible over most of the range of $\xi$. 

094509-15
used in our fits. Further, the total corrections to \( m_\pi \) are small, being less than \( \sim 15\% \) over the full range of quark masses. In contrast, the corrections to \( f_\pi \) become substantial at the heavier pion masses, exceeding \( \sim 50\% \) at the heaviest mass considered. Further, at the modest value of \( \xi \approx 0.08 \) the NNLO corrections become significant compared to the NLO corrections.

In the left panel of Fig. 8, the determination of \( \bar{I}_3 \) is shown. The results of the fixed lattice spacing \( \chi \)PT analysis from Sec. IVA 2 is displayed, as well as the continuum extrapolated value. Also shown are the values extracted from MA\( \chi \)PT at NLO, and from NLO MA\( \chi \)PT supplemented with continuum NNLO \( \chi \)PT, as discussed in Secs. IV B 1 and IV B 2, respectively. The results of the MA\( \chi \)PT analyses are consistent with the continuum extrapolated results, but with smaller uncertainties. This is not surprising as the mixed-action framework allows a simultaneous treatment of calculational results from multiple lattice spacings. This consistency lends confidence in the entire analysis. In the right panel of Fig. 8, the extraction is compared to the original estimates by Gasser and Leutwyler [2] as well as to the recent lattice QCD average [12]. In Fig. 9, the analogous results for \( \bar{I}_4 \) are displayed, although Ref. [12] does not provide an average value (citing insufficient reporting of the associated systematic uncertainties).

FIG. 8 (color online). The present determination of \( \bar{I}_3 \) (left panel), and its comparison to the lattice QCD average value [12] and phenomenological results (right panel). Some of the \( \bar{I}_3 \) results in the left panel have been given small offsets in \((b/r_1)^2\) for presentations reasons.

FIG. 7 (color online). The NLO and NNLO contributions to \((m_\pi^2/2Bm_q - 1)\) (left panel) and \((f_\pi/f - 1)\) (right panel). Both of these quantities vanish in the chiral limit. The larger (red) dashed curves are the NLO contributions and the smaller (blue) dashed curves are the NNLO contributions. The solid (black) curve is the entire NLO + NNLO value.
V. RESULTS AND DISCUSSION

We have performed precision calculations of the pion mass and the pion decay constant with mixed-action lattice QCD. Calculations using domain-wall valence quarks and staggered sea quarks were performed on a number of ensembles of MILC gauge-field configurations at different light quark masses, two lattice spacings, different volumes and different extents of the fifth dimension. Using the two lattice spacings and the multiple light quark masses, the results of these calculations were extrapolated to the continuum, to infinite volume and to the physical pion mass. Ideally, continuum extrapolations would be performed with more than two lattice spacings. While this is not possible with the present numerical results, the two methods used to quantify uncertainties associated with the continuum extrapolation from the two lattice spacings used in this work are found to give the same results within uncertainties. One method involved using two-flavor $\chi$PT to extract the LECs, which implicitly include lattice-spacing artifacts. LECs calculated at two different lattice spacings were then extrapolated to the continuum. It is found that NLO $\chi$PT fails to describe the results of the Lattice calculations of $m_\pi$, while NNLO $\chi$PT appears to be consistent with them. The second method was to use MA$\chi$PT where the lattice-spacing artifacts are explicit, and the extracted LECs are those of the continuum, up to higher order contributions. A hybrid analysis was motivated to be sufficient, where the mixed-action NLO contributions were combined with continuum NNLO contributions to provide reliable extractions of the LECs. These analyses have provided determinations of the Gasser-Leutwyler coefficients $\bar{l}_3$ and $\bar{l}_4$,

$$\bar{l}_3 = 4.04(40)(^{33}_{{43}})\text{ and } \bar{l}_4 = 4.30(51)(^{84}_{{60}}).$$

These values are consistent with the (lattice) averaged values reported in Ref. [12]. Our analysis also provides

$$\frac{f_\pi}{f} = 1.062(26)(^{42}_{{40}}),$$

which is to be compared to the lattice averaged value of $f_\pi/f = 1.073(15)$. Combined with the experimental value for $f_\pi^{\text{exp}} = 130.4$ MeV, a value of $f = 122.8(3.0) \times (4.8)\text{ MeV}$ is found (we have not accounted for explicit isospin breaking effects, but these are expected to be small). In Table XV, the present results are compared with those of the most recent calculations from other lattice collaborations. Further, the extrapolated value of $r_1 f_\pi$ and the experimentally measured value of $f_\pi$ provide a determination of the physical scale $r_1$,

$$r_1 = 0.306(9)(^{10}_{{14}})\text{ fm},$$

which is to be compared with the MILC determination (on the same ensembles) of $r_1 = 0.311(2)(^{3}_{{5}})\text{ fm}$. It is interesting to note that, despite greatly enhanced statistics on the same ensembles of MILC gauge-field configurations, the uncertainty that we have obtained in the calculation of $f_\pi$ is somewhat larger than that obtained in Ref. [17].

The systematics in the calculations arising from the finite lattice volume and from residual chiral symmetry breaking due to the finite fifth-dimensional extent of the domain-wall action have been explored and quantified. Previously, residual chiral symmetry breaking contributions were identified to be the dominant source of uncertainty in lattice QCD predictions of the $I = 2\pi\pi$ scattering length [25]. While the present analysis has not been able to precisely determine these effects, the analysis resulted in constraints on the size of these contributions,
importance of higher orders in the results of the lattice QCD calculations, suggesting the contributions to the pion mass appear to be incompatible with the I = 1/2 which in turn can be used to reduce the uncertainties in the I = 2πτ scattering length predictions.

The predicted NLO mixed-action finite-volume contributions to the pion mass appear to be incompatible with the results of the lattice QCD calculations, suggesting the importance of higher orders in the \( \text{MAXPT} \) expansion. A 30% systematic uncertainty is assigned to the NLO finite-volume contributions to account for NNLO effects, leading to a consistent description of the results.

In Table XVI the contributions to the total uncertainty from the various systematics are displayed. While the discretization and residual chiral symmetry breaking effects have some impact on the determination of the LECs, it is clear from this summary table that the dominant uncertainty is due to the chiral extrapolation. Having further numerical results at lighter pion masses is the single most important systematic to address to improve upon the present work.

In conclusion, we have found that a careful two-flavor low-energy effective field theory analysis of the lattice QCD calculations of the pion mass and its decay constant can reliably determine the NLO Gasser-Leutwyler coefficients, \( \hat \ell_3 \) and \( \hat \ell_4 \), which are found to be in good agreement with the average of other determinations. In particular, mixed-action chiral perturbation theory which includes lattice-spacing artifacts explicitly, provides a reliable framework with which to perform chiral extrapolations of the physical light quark masses, and to determine \( \hat \ell_3 \) and \( \hat \ell_4 \).

\[
\hat \ell_3^{\text{res}} = 17(5)(10)^0, \quad \hat \ell_4^{\text{res}} = 0(11)(12), \quad (44)
\]

which in turn can be used to reduce the uncertainties in the \( I = 2\pi \tau \) scattering length predictions.
